You should know that relying strictly on the APRS infrastructure on 144.39 is no guarantee of a successful recovery. Once the payload string descends below the radio horizon of the nearest digi or I-gate, you're out of the system, and you'd better have a closer tracking and recovery station that can hear you beacons. Quite often, although the APRS packet signal can be heard from a payload on the ground, it's too weak and noisy to decode. ANd the packet bursts are too brief to allow for a decent DF bearing. This is where you need a separate, independent DF beacon on the flight string that transmits a steady signal for 15 to 30 seconds every minute or so, with a CW ID, of course, that you can DF on. Many of EOSS's recoveries still rely on some DFing if the landing site is way out in the boonies. By "independent" I mean a completely separate payload that doesn't share power, radio, computer or antenna with your APRS beacon, since any of those can fail and bring both beacons down.

Please don't take any of these suggestions as criticism, Brenden. We're just trying to give you the benefit of some of the lessons that we've learned the hard way, and we sincerely hope that your next flight results in a quick recovery and some great in-flight pix. As a science fair judge myself, it's my opinion that if you present your flight and its results in a half-way careful fashion, you'll be on your way to the regional and perhaps even the state fairs!

The term "balloonsat" was created by Chris Koehler back in 1999 or 2000,
when he was the newly hired Dir. of Colo Space Grant. It was coined from
NASA's "cubesat" specification for student experiments that could be
put into orbit as ballast on NASA launches or from the Shuttle. Amongst
other things, a "cubesat" was required to be a 10cm x 10cm x 10cm cube,
which is the form factor that Chris adopted for his "Gateway to Space"
undergrad course at CU back then. Sometime later, Chris developed his
Space Grant Balloon Workshop, where faculty from other Space Grant colleges
learned how to develop their own versions of the "Gateway" course, including
building and flying kit-built balloonsats.

EOSS is proud to have been tapped to operate all of the Gateway and
Workshop flights since then.

From: Mike Manes
Topic: 7915 Message: 7942

Hi Carlton,

Prior to the GPSL flights, there were no active I-gates in the Hutch area
on 144.39, and the only I-gates that put EOSS-154's 144.34 beacons into
findu were in TX! So it's important to set up I-gates in advance if
you're gonna operate off the 144.39 backbone.

Another way to deal with this is to put a low-rate beacon on 144.39 (no more than once per minute and no more than a WIDE2-1 path) and do whatever you want on 144.34 or 144.36. You can track on a clean frequency (no terrestrial digis stomping on your balloon packets) and if that one fails you have the other on the national network with I-gate support.

Redundancy is good, but it does cost money and weight.

From: Brenden Geary
Topic: 7915 Message: 7944

I am in a ham club (http://www.w6ier.org/) and yes I was welcomed with open arms. They tried to put a link to my site on the home page but it's a dead link. I am trying to help them out but I think they are a little worried about a kid working on their site. I usually have a large group for my launch and nobody in the landing zone, everyone wants to watch it take off. Having a group in the predicted landing site is a great idea, I will see if I can get some people to monitor the predicted landing site. I didn't take any of your suggestions as criticism, I am on this list just soaking up the knowledge. As far as presenting my results in a half-way careful fashion, here are my ideas:
Show the predicted flight path vs Actual flight path
Display Boyles law which and explain why it makes the balloon pop
Graph Time vs Barometric Pressure
Graph Time vs humidity

Graph Time vs Temp inside and outside the payload
and of course the eye candy pictures at altitude.

What do you think of my project? Anyone please feel free let me know what you think... its all good.

Hi Brendan,

I don't think that either ham radio or ARHAB is dying off. Many new hams

get their tickets in order to enjoy perhaps a small sliver of the ham

radio hobby, such as ARES or ARHAB, and later discover more and more of the

vast array of activities offered by the hobby, such as DXing, microwaves,

ARDF, etc. I'm sure that if you were to join up with a ham club in your

area, you'd have a chance to see what I mean.

EOSS actually sprung forth from a ham club called Western Vision Network,

a Denver-area group of hams who specialized in ATV (amateur television). A

few of them, inspired by Bill Brown's pioneering work, decided to fly an

ATV transmitter and camera into the stratosphere. So EOSS-1 was actually WNV-1, but WVN died off years ago.

You're right about ARHAB not dying off - if anything, it's growing like Topsy! 20 years ago, there were just a handful of balloon groups in the US, and none overseas. Today, there at least that many coming into the fold every few months!

By the way, I may have hinted in an earlier response at one of EOSS's secrets to its recovery rate: have a tracking and recovery team already deployed when the balloon launches. Although ARHAB can be a "one man game", it's a lot more fun, and less costly, if you gather a team to work with you. Which points back to my earlier point about joining a ham club. I assure you that a young fellow such as yourself will be welcomed with open arms by some of those old timers who got their first tickets about your age - but back in the vacuum tube era.

I think you typoed "154.39" in your earlier email - you meant 145.39 didn't you?

You should know that relying strictly on the APRS infrastructure on 144.39 is no guarantee of a successful recovery. Once the payload string descends below the radio horizon of the nearest digi or I-gate, you're out of the system, and you'd better have a closer tracking and recovery station that can hear you beacons. Quite often, although the APRS packet signal can be heard from a payload on the ground, it's too weak and noisy to decode. ANd the packet bursts are too brief to allow for a decent DF bearing. This is where you need a separate, independent DF beacon on the flight string that transmits a steady signal for 15 to 30 seconds every minute or so, with a CW ID, of course, that you can DF on. Many of EOSS's recoveries still rely on some DFing if the landing site is way out in the boonies. By "independent" I mean a completely separate payload that doesn't share power, radio, computer or antenna with your APRS beacon, since any of those can

fail and bring both beacons down.

Please don't take any of these suggestions as criticism, Brenden. We're just trying to give you the benefit of some of the lessons that we've learned the hard way, and we sincerely hope that your next flight results in a quick recovery and some great in-flight pix. As a science fair judge myself, it's my opinion that if you present your flight and its results in a half-way careful fashion, you'll be on your way to the regional and perhaps even the state fairs!

Use video if you can. A small digital video camera will show the balloon bursting. You could also use the main lifting balloon as part of your Boyle's law experiment. A video camera of that burst is spectacular.

For educational laughs, send up a bag of chips and record it expanding and bursting.

7946. Payload box construction for high altitude flight

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-04 21:50:49 UTC
From: k6rpt
Topic: 7946 Message: 7946

Currently my payload box has 1 ½" foam walls with a locking lid. I put it in the freezer that has a temperature of -5 to 0 degrees, and in 2 hours the internal temperature dropped from 70 to 5 degrees. I flew this same payload box to 105k feet with no problems, all equipment continued to work fine. I didn't think the internal temperature would drop so quickly. I'm running these tests because my upcoming high altitude attempt that will be in near space an additional 30 to 45 minutes longer than the average flight.

How thick should the foam walls be for a high altitude flight that will be in near space 30 to 45 minutes longer?

What is a safe internal operating temperature for the Garmin GPS 18 LVC and a Micro-Track 8000 FA?

-Ron K6RPT

7947. Science fair

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-04 21:55:12 UTC
From: Mike Manes
Topic: 7915 Message: 7947

Hi Brenden,

Well, shucks! It sounds as though you've got The Right Stuff to make your next flight a success! Just a few tips:

1. Back off on your APRS xmit power - the Alinco DJ-Cx series of credit card HTs have served EOSS excellently for years. They work fine from regulated +5Vdc, which may be the same source used by your GPS and flight computer.

2. Although "things should be made as possible, but not more so" does apply to the guts of your payload. Don't skimp on mechanical robustness of the stuff on the outside, however. PBC and a windy landing can break off antennas and break open weak enclosures. A good test is to kick the payload down a flight of stairs.

3. Cold soak you payload with power off in a food freezer at 0F (-16C) for about 4 hours, powered off. Then see if it powers up and runs OK.

4. Do run a separate backup beacon.

Now, I can understand everyone's wanting to watch the launch. And for a summer flight, where the landing isn't far from the launch site, that's OK. But in the winter, after the upper winds turn westerly, it's best to have your trackers out in the field at launch. Shanghai a videographer to film your launch to show the trackers, and trade it for a video of the descent and landing :=).

For your mission, recovery of your payload(s) intact is critical, so don't give Murphy an even break there.

Some suggestions for your science fair presentation:

Instead of just Boyle's Law, use Archimedes law to show why a balloon rises in the atmosphere. Might also show the how the lift of different gasses compare (some may be surprised that H2 isn't much better than He).

Use time as your independent variable only for GPS altitude. Explain why the ascent rate is nearly constant, while the descent rate under the parachute is exponential.

Plot your various in situ air measurements vs. altitude rather than time. Point out and explain the tropopause level.

Explain the time lag between internal and external temperature.

Note that relative humidity sensors are pretty temperature-sensitive, and most just won't work at all below freezing. Consider instead using a UV-sensitive photo-detector to show how UV solar intensity varies with altitude.

A common CdS photocell and UV filter in a resistive divider network feeding
the analog input of your logger should work.

Be sure to point out stuff that all this data taught you - that's something
judges look for, and as a bonus, where you hope to go with future flights.

And of course, the highlight of your display should be those photos of the
limb of Earth against the blackness of space!

I run with 3/4 inch thick walls and don't drop below 32 *F except early during descent. Exterior color does make a difference. Do you have dark colors on the exterior?

Hi Ron,

EOSS uses 1/4" foamcore for its payload enclosures, and the lowest internal air temp we've seen internally is about zero F. Note that as the air gets thinner, its capacity to carry heat away is diminished, so don't fret. If your payload guts powers up and operates OK after a 2-4 cold soak at -16C (zero F), then you'll be OK - and if you're dissipating more than a few watts internally, you may even find that those 1.5" foam walls are overkill for a typical 2.5 hr trip to 100K' and back down, provided the entire flight is during the day - things can get a LOT colder over night with no solar flux.

We generally run 1/2 or 3/4" walls and have had no problems staying above about -3C. Most electronics are good for -20C to -50C. The batteries are typically the limiting factor.

Lithiums (primary and rechargeable) seem to be good for well below freezing.

From: Mike Manes
Topic: 7915 Message: 7951

Since EOSS operates off the 144.39 backbone, we don't sweat overloading the infrastucture. In fact, the AE0SS-11 and KC0YA-11 APRS modules both use the digi alias of EOSS, and our tracking teams use adaptive beaconing via EOSS. That allows all of us on the ground to see where the trackers are in near-real time, and when we fly a two-fer, the 2nd balloon also digipeats the landing spot of the 1st one - too cool!

The freq DOES get pretty busy, but then again, we're the only ones there, and with just 300 mW to a J=pole, we're not gonna be QRMing folks out at the radio horizon - for long anyway.

All it takes is one or two decent I-gates set up in advance on 144.34.

7952. RE: [GPSL] Payload box construction for high altitude flight

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-04 23:08:26 UTC
From: Meer, Stephen
Topic: 7946 Message: 7952

A trick I use with the K0SCC payloads is to heat the batteries in a standard heating pad to 90 degrees F prior to sealing them into the payload envelope. The thermal mass does wonders for keeping the temp up.

One of my flight packages is a GPS relay that consists of a Garmin 15 series GPS board, a Digi ZigBee RF deck and a small AVR processor. The entire package will run for a couple of days from a single alkaline 9 volt battery at normal room temp. The exterior package is constructed from ½ inch foam core board and has an internal volume of approximately 36 cubic inches. My experience is that I can heat the battery to 90 degrees, seal it in, fly it and after recovery about 4 hours later the battery is still more than a little warm to touch.

The payload box is white and Northern California TRACON wants me of the ground by 5 ☐ 5:30am. I would assume that I would still benefit form solar heat if I painted the box black with Krylon foam safe paint. Will Krylon paint block RF for the GPS to receive?

Brendon.

Here at Near Space Sciences, we have people down range also waiting for the payload to come to them. To the predicted landing site. The last dozen flights of so every flight has been watched come down under the parachute. Their goal is to actually catch one. They haven't done that yet but have come withinn 10 yards of doing it. he was sooo mad! he he he. but down range in the winter.

But in the summer months especially during turnaround months. Most of our chase crew are at tha launch site to watch it leave. There is plenty of time to get into the landing area when it's not that far away.

I always thought half the fun was trying to beat the payload to the site of impact!

>>
>> I am in a ham club (http://www.w6ier.org/) and yes I was welcomed with open arms. They tried to put a link to my site on the home page but it's a dead link. I am trying to help them out but I think they are a little worried about a kid working on their site. I usually have a large group for my launch and nobody in the landing zone, everyone wants to watch it take off. Having a group in the predicted landing site is a great idea, I will see if I can get some people to monitor the predicted landing site. I didn't take any of your suggestions as criticism, I am on this list just soaking up the knowledge. As far as presenting my results in a half-way careful fashion, here are my ideas:
>> Show the predicted flight path vs Actual flight path
>> Display Boyles law which and explain why it makes the balloon pop

>> Graph Time vs Barometric Pressure
>> Graph Time vs humidity
>> Graph Time vs Temp inside and outside the payload
>> and of course the eye candy pictures at altitude.
>>
>> What do you think of my project? Anyone please feel free let me know what you think...
its all good.

7957. Re: [GPSL] APRS abuse

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-05 01:35:42 UTC
From: Sheri Barton Trbovich
Topic: 7915 Message: 7957

Sorry, hit the send button too soon. I like Zack's comment, in our group there are some who think we should all wait until the payload lands before we go out. I disagree and like to chase.

Sheri, WB1SAR, HARBOR at Weber State Univ.

Sent from Sheri and Ian's iPad.

On Aug 4, 2010, at 7:25 PM, Zack Clobes <zclobes@...> wrote:

>>
>> I am in a ham club (http://www.w6ier.org/) and yes I was welcomed with open arms. They tried to put a link to my site on the home page but it's a dead link. I am trying to help them out but I think they are a little worried about a kid working on their site. I usually have a large group for my launch and nobody in the landing zone, everyone wants to watch it take off. Having a group in the predicted landing site is a great idea, I will see if I can get some people to monitor the predicted landing site. I didn't take any of your

suggestions as criticism, I am on this list just soaking up the knowledge. As far as presenting my results in a half-way careful fashion, here are my ideas:
>> Show the predicted flight path vs Actual flight path
>> Display Boyles law which and explain why it makes the balloon pop
>> Graph Time vs Barometric Pressure
>> Graph Time vs humidity
>> Graph Time vs Temp inside and outside the payload
>> and of course the eye candy pictures at altitude.
>>
>> What do you think of my project? Anyone please feel free let me know what you think... its all good.

7958. GPSL Photos

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-05 02:23:22 UTC
From: Zack Clobes
Topic: 198 Message: 7958

I've posted the photos for my website.

http://picasaweb.google.com/projecttraveler/GPSL2010HutchinsonKS#

I'm working with Keith to try to get the PPT's and the WebEx recordings posted yet this week.

Zack Clobes, W0ZC

7959. Re: [GPSL] APRS abuse

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-05 02:29:18 UTC
From: Mike Manes
Topic: 7915 Message: 7959

Except when it's 100 miles downrange and accessible only via dirt (or mud) roads :=(.

"Things should be made as simple as possible, but not more so."
A. Einstein

7960. Re: [GPSL] APRS abuse

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-05 02:38:20 UTC
From: Mike Manes
Topic: 7915 Message: 7960

Hi Sheri,

Well, next winter flight, let 'em be while you go fetch it back, and see if
they can find it.

Being on site during the landing also ensures just who will do the recovery.
On one ES-OS flight, some locals got there first and spirited it off to
their place in the nearby town. It was located only by the glint of sunlight
from the AOL CDs on the flight string passing between back yard fence pickets.
On another, the EOSS recovery team arrived moments after landing only to find
some citizens already over the fence.

If all else fails, be sure to include a "return to sender" label on the
payloads.

When is sunrise at your launch site? If you fly before sunrise, you'll
need a strobe light if you're non-exempt. If you're exempt, then it's
still a nice touch.

BTW, how close to Class B airspace (SFO?) are you flying?

Given the thickness of your walls, I doubt that much heat will pass from
solar flux absorbed by the outer walls will make it inside. And most paint
pigments aren't very good IR absorbers. You'd be better off painting it
a fluorescent orange to make it easier to spot in the field. The best solar
absorptive paint uses carbon black pigment, and that might attenuate the
GPS sigs. If so, then just move your GPS antenna to the top of the box.
Or just leave the top unpainted.

Brenden,

I advised local 8th grade student Jodie Tinker for her Science Fair high altitude balloon...she ended up winning 1st place in her category in the Alabama State Science Fair this year as well as 10 additional special awards...it's a great way to showcase Earth's environment all the way up to the very edge of Space and is a great Science Fair topic.

I'm currently traveling in Indiana preparing for this Friday's balloon flight for students attending the Spaceport Indiana science camp...when I get back home I'll send you some photos from Jodie's flights earlier this year.

Subject: [GPSL] Science fair

Hi Brenden,

Well, shucks! It sounds as though you've got The Right Stuff to make your next flight a success! Just a few tips:

1. Back off on your APRS xmit power - the Alinco DJ-Cx series of credit card HTs have served EOSS excellently for years. They work fine from regulated +5Vdc, which may be the same source used by your GPS and flight computer.

2. Although "things should be made as possible, but not more so" does apply to the guts of your payload. Don't skimp on mechanical robustness of the stuff on the outside, however. PBC and a windy landing can break off antennas and break open weak enclosures. A good test is to kick the payload down a flight of stairs.

3. Cold soak you payload with power off in a food freezer at 0F (-16C) for about 4 hours, powered off. Then see if it powers up and runs OK.

4. Do run a separate backup beacon.

Now, I can understand everyone's wanting to watch the launch. And for a summer flight, where the landing isn't far from the launch site, that's OK. But in the winter, after the upper winds turn westerly, it's best to have your trackers out in the field at launch. Shanghai a videographer to film your launch to show the trackers, and trade it for a video of the descent and landing :=).

For your mission, recovery of your payload(s) intact is critical, so don't give Murphy an even break there.

Some suggestions for your science fair presentation:

Instead of just Boyle's Law, use Archimedes law to show why a balloon rises in the atmosphere. Might also show the how the lift of different gasses compare (some may be surprised that H2 isn't much better than He).

Use time as your independent variable only for GPS altitude. Explain why the ascent rate is nearly constant, while the descent rate under the parachute is exponential.

Plot your various in situ air measurements vs. altitude rather than time. Point out and explain the tropopause level.

Explain the time lag between internal and external temperature.

Note that relative humidity sensors are pretty temperature-sensitive, and most just won't work at all below freezing. Consider instead using a UV-sensitive photo-detector to show how UV solar intensity varies with altitude. A common CdS photocell and UV filter in a resistive divider network feeding the analog input of your logger should work.

Be sure to point out stuff that all this data taught you - that's something judges look for, and as a bonus, where you hope to go with future flights.

And of course, the highlight of your display should be those photos of the limb of Earth against the blackness of space!

Brenden,

It's not bogus info -- care must be given when selecting a frequency. The best bet is to avoid frequencies that are commonly used for other things (like ATV Talkback on 144.34), and to find a frequency where the mode that you're using is commonly used. APRS, when sent on VHF, typically uses 1200 baud packet. Therefore it would be logical to put it on a packet frequency. Check the band plan or repeater frequency coordinator for your state / section, and any surrounding states / sections that may be in the "footprint" of your package when it's at altitude (this may be several hundred miles). In many (most?) parts of the country the dedicated packet frequencies are 145.01, 145.03, 145.05, 145.07, and 145.09. The following are also commonly used: 144.99, 144.97, 144.95, 144.93, 144.91. But again, check the band plan for your area and check with the frequency coordinator to make sure the frequency you choose will not interfere with other users such as a voice repeater input.

It should be noted that 144.99 is the more-or-less nationally accepted "alternate" APRS frequency so it is ideal for things such as balloon flights that want to use higher rate (10 second, or even 5 second or less) update rates without causing any strain on the 144.39 network.

-Jerome, W0JRT

--- In GPSL@yahoogroups.com, Brenden Geary <bjgeary@...> wrote:

> I live in Southern California and trust me I can see the congestion on the APRS network.Â I thought I was being smart by trying to use a freq other than 144.39 like 154.39 and use my D700 to track it myself.Â I was told that I shouldn't do this because even if this
freq is open in my area, it may not be when I get to altitude when my signal will go for 100's of miles.Â I this bogus info?

There may be carbon in black paint, but I don't think that's a problem. I cover my airframes in black fabric.

One thing to try is to pre-heat the interior with a hair drier.

Or as in our foil covered boxes we have done Both.

Mount the antenna on the outside, (never had one freeze up yet)
or
mount it inside but leave a window of un painted area large enough that
it can see 90% of the sky. (this has worked fine also)

That Ghost is pretty cool!

Has anyone made any sort of a summary?

Like who flew what on what size balloon with payload weights etc.?

Hi Mike,

Sunrise is at 6:15am and the payload weight is 10 ounces, so I'm exempt. The strobe won't work out because I'm going for an altitude record and the weight would be unacceptable. I will be launching from San Jose, CA, so the concern is San Jose international air port. This mission will be a non-recovery mission so I'm not concerned with the color for finding it. Good point about the solar heat not making it through the walls.

A good old fashioned heating pad like you would use on an injured body part. The one I have on it's lowest setting sets at about 100 deg F so I wrap the battery in it for a bit and then take the battery out and measure the temp with an IR thermometer. I do this a couple of times to make sure that the entire mass of the battery is at temp.

Obviously this required 110 VAC being available at the point you plan to do final prep and packing of the flight package. I use an AC inverter in my vehicle or a wall plug at the ground station when available.

7972. Iowa Balloon Flight of 8/5/10 (or not)

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-05 21:31:28 UTC
From: Pete Lilja
Topic: 7972 Message: 7972

Today my buddy Greg, W0GRB, and I made some last minute plans to launch a HAB from west of Britt, Iowa.

I drove the hour or so to Greg's house and we loaded up my car with the needed supplies, hardware, gas and 'stuff' needed to fly. The location chosen is at a friend of Greg's agricultural tire and repair / welding shop just west of Britt on Hwy 18 in north central Iowa. It's a great spot as it's wide open and has a large building to protect us from the wind. That, and the flight prediction showed the landing spot about 15 miles from my house which made it easier for me on the way home.

We got all of our flight equipment turned on, tested and loaded in to the payload box. Despite my admonishing him many times not to use the 50lb Spider Wire fishing line to tie between the balloon and the parachute Greg insisted. Spider Wire has little stretch, can break and it is very abrasive. Greg had used this line on two previous flights with success but the last time the abrasive Spider Wire cut the meaty part of the outside of his palm which really hurt, I'm sure. To counter that this time he made a slick little dog-leash hasp thing with a wrist strap to slide down the line line to the 'chute as the balloon went up just prior to release. We got the balloon filled even though we did have to fight some wind. A double check on the radios and cameras was a 'Go' so Greg snapped his little dog-leash hasp doohickey on the line and let the balloon climb. Just as he got to the end of the line and the top of the 'chute the line snapped!

Yeow! The filled balloon took off like a shot and climbed out rather quickly. We both stood with our mouths agape at the sight! I looked at him and he me when he immediately said "Don't say nothing." We'd never lost a balloon before and had even had this one safety tied to the ground.

Well, as luck would have it I brought along a spare 1200 gram balloon "just in case." I asked Greg how much gas was left in the helium tank and he said "I dunno" and "I'll ask if they have a gauge in the shop." A few minutes later he came back with the gauge and said that they had a tank of helium, too, if we needed more. My thoughts were "Great!" we can fly. Since we only had 500 lbs. in the first tank Greg went and got the second. I tied some *nylon cord* to the parachute and inserted a machined PVC bung plug we use for filling and tying of to the payload. These plugs have worked really well on previous flights. I was a happy HABer. What are the odds of flying from a place where you had just lost a balloon that has a tank of gas available to use? Amazing.

By now the winds had pick up and maybe shifted a bit exposing our nice sheltered area a little more. But we quickly got to work and filled the second balloon. I was thinking we were getting to the point of stopping the fill to check its lift against a jug of water to make sure we'd have a good

ascent rate with a proper amount of lift. I was holding the bung / filll hose in my right hand and had my left hand around the thick latex of the balloon's neck. I'd been fighting the increasing wind and controlling the balloon with my left had. A sudden wind gust came up and, I think, twisted the balloon's neck closed as I squeezed putting a death grip on the neck of the balloon with my left hand. Not seeing what was happening Greg kept the gas flowing. Before I knew it and almost instantly the thick, latex neck of the balloon expanded like a 10" diameter sausage about 3 feet long! Then "BANG!" and the bung-plug blew out the end and my former death grip was now useless. The second balloon floated away! TWO BALLOONS LOST for one attempted flight!

I ripped off my latex gloves, uttered a few unmentionables and walked a few paces away mouth again agape at the spectacle before my eyes. I caught my breath and we both began laughing as this was just too unreal to believe.

We packed up our stuff in the car all the while discussing the events. We decided the adage that 'if it worked every time it wouldn't be as much fun' is true. And that, while simple in concept, High Altitude Ballooning is fraught with peril and challenge. It is no small feat to pull off a successful HAB flight. Over lunch we also agreed that while losing two balloons and gas in this way wasn't a pleasant experience what we did lose were the expendables of a flight anyway. All of the reusable gear we still had in hand.

As is often the case we learned a few things from these mistakes. Primarily for me is that wind sucks (or blows, depends on your perspective). Having a back-up balloon isn't always a good thing! You need gas too! Launching from a shop that has 'extra' gas is a good thing! I hope Greg learned Spider Wire is for fishing and not HABing.

No real harm done with this 'flight.' I suppose it could happen to anyone. I just want it to be someone else next time!

After all of this we did release a 100 g pilot balloon with a small, plastic Coke bottle with an information card inside. Maybe someone will find it and call.

I paid the shop for the gas we used and we headed home...slightly embarrassed but with plans to get some more balloons and lifting gas.

I hope your day is a good one!

Pete

Hi Pete,

Anyone of who's claimed to have executed a perfect flight must have
found a mess of that funny weed ...

Lessons learned (and as often forgotten):

1. 50 lb tensile strength does NOT equal 50 lb impact strength.

2. Use screw-type hose clamps to secure a 1200 gm neck to the fill rig.

3. Keep the fill rate real gentle until the balloon lifts itself off
the deck firmly, and let the guy on the valve watch for twists.

The good news is that you didn't lose your payloads :=)

On our 154th flight, EOSS had a neck blowout during fill. The fill tube
was only inserted a few inches, and the balloon handler took a grip just
above the top of the fill tube - a bit too tight of a grip, turns out.
Fortunately, the handler still had a grip (talk about keeping one's cool!),
and we were able to execute a re-insertion into the remaining neck to complete
the fill and flight.

We've used a combination of 50# mono and 50# spider wire in parallel for a good 10+ flights now, with no trouble. The first couple we used just 50# mono, but for some reason it got brittle on us one morning where I could literally crumble it in my hands (we lost a balloon to it). Never before and never again have we seen that behavior, even off the same spool. The only thing I can think of was a manufacturing defect at one spot.

After losing the balloon, we started flying a double loop with the mono holding the weight, and the spider wire just in case, although both links have always come back intact.

We have also started using kite string lanyards run through a ring at the neck of the balloon. That lets us ease the weight of the packages onto the load line without a lot of jerking around. That's worked great except when 1) the lanyard is allowed to wrap around the nylon load line and 2) the lanyard holders aren't equipped with scissors for cutting lose (just in case).

For the record, I'm not sure that we've ever flown more than about 7lbs of payload.

This story reminded me of one NSTAR launch attempt in 2004, which had the "neck sausage" and premature flight too. I uploaded the video to YouTube (rated PG):

http://www.youtube.com/watch?v=FE8SPugjtwM

Not our first loss either - we've had two other balloon launches unencumbered by those pesky payloads.

I told my buddy many, many times about that 50# impact strength being a rather nebulous thing and just use some nylon cord. He'd had two successful flights prior using the Spider Wire so he was thinking it's the cat's meow. He (like me, I suppose) can be hard-headed about things and since the payload was carrying his radios, cameras and GPS as well as helium he'd purchased I can only push so far.

And, yep, all that was really lost was a little pride and the expendables in a balloon flight.

Oh, man, that was very similar to what happened to us today. Sorry, but I
am laughing as I know the feeling of that as it's fresh in my mind!

Thanks for posting, Mark.

Attachments: 1 described; binary payloads are missing from this source WARC

NSS-1,,, err well NSS-0 was a similar event. except it was a bad knot
between the balloon line and the top of the parachute.

the balloon was going up and suddenly the parachute was on my head.

Never used those recommended knots ever again.

Criminy Dutch! With that much wind in the AM, I'a gone back to bed and
flown another day ...

What's amazing is that the neck bubbled out several times without blowing
out. Not sure what happened to "unencumber" it, though. Did the neck just
break below the ring? (PG, indeed :=P).

I had some "Rope" person and a highly respected kite manufacturer
recommend this one knot.

Obviously it did not work very well.

I developed this one knot never found it online anyplace, or even it it
has a name. but i can even tie it with one hand while holding the
balloon in the other. and it's never ever failed me. matter of fact
the harder you pull on the knot the tighter it gets.

From: L. Paul Verhage
Topic: 7984 Message: 7984

Most of use fly within the 12 pound limit so we don't need to file for a wavier.

However, I'd like to know how heavy we do get. What's the other end of the spectrum look like in regards to weight and altitude.

Thanks.

PS, I was reading a COSPAR report written by a Japnese company about their development of thin, lightweight plastic films. They built a balloon that reached 170,000 feet several years ago. Small payload and large balloon.

I see that some of the ZPB are several million cubic feet in volume.

Some of you did and many of you probably did not read my long monologue on our two lost errant balloons yesterday. That's really neither here nor there but is prompting this question...

...helium regulators: the regulator we use is simply a guy on the tank with his hand on the valve regulating flow. After that 'sausage neck' experience yesterday I'm now wondering about a regulator. How do they work? Do they regulate pressure? Flow? Both? Or is one a product of the other? I'm really only practically familiar with demand type self contained breathing apparatus regulators and now that I think about it I'm not so sure how really they do regulate.

Also - where do you purchase a helium regulator? I imagine my gas supplier would get a premium for one.

Wasn't there some recent discussion about adaptors for hydrogen to helium regulators as well?

After losing a $65 balloon yesterday due to too much pressure and / or flow maybe the expense of some proper equipment is in order.

Pete

The regualtor I use is inexpensive. It doesn't regulate the pressure delivered to the balloon, it just indicates the pressure in the tank. I still use the valve on the tank to control the flow of helium.

Check my online book (free at Parallax) for information on making a filler.

We run H2, and fill with a very low pressure, usually 5 PSI max.

Now will 5 PSI make the situation you had? I don't know.

But yes pressure and flow are all related. Higher pressure faster flow.

And the regulator does indeed regulate the pressure, so in our setups,
if we were to kink the neck and built up 5 PSI the flow would stop.

Now what does 5 PSI in that thick neck section look like I have no clue.

I use an oxygen regulator, got it at my gas supplier. Probably overkill, it's a two-stage regulator.

You could adapt a standard helium party balloon filler to the same purpose. The main thing I like is a reading of the tank pressure, so I can approximate the volume of helium I'm using. Knowing a standard T cylinder holds 290 cu ft at 2600 psi, you can work out the cubic footage vented by the pressure reduction. The fitting are standard pipe fittings and you should easily be able to adapt to barbs for an oxygen fill hose.

You may be best off getting the party balloon filler on eBay (can be had for ~$30) and taking it to your gas or welding supplier and saying "I need fittings to adapt this to a length of oxygen hose".

We don't use any kind of regulator - just tap straight off the bottle with a hose.

EOSS had a neck vs. helium episode at GPSL. I was about a hundred feet away and thought it sounded like a gun shot. Can anyone from there give us some input?

I was wanting to ask anyway, for those using Hydrogen, is there any particular reason that you use a regulator on that side above and beyond why you'd use it on the Helium side?

I use a party balloon regulator I bought on ebay. The regulator has a 1/4 pipe fitting that has the party balloon filler on it. I took that bend valve off and added a ball valve and hose to the regulator.

The regulator output is still high enough to pop the neck but low enough you can use a standard brass ball valve on the output. I believe it is around 30PSI. I like the ball valve because in a emergency you can slam it shut in less than 1/4 turn.

Hi Pete

We use a party balloon regulator commonly found on eBay. From there we attach a 25 foot air compressor hose and an air compressor quick connect. From there we have a very interesting series of adaptors that take us from an air compressor quick connect to a standard plumbing ball valve and finally to a PVC filler pipe. This gives the person filling the balloon control over the gas flow. It also lets use disconnect the fill hose to measure the lift. The attached picture shows the setup before we added the quick connect coupler.

Hi Mark,

?

?? Here in AZ ANSR started with a party balloon filler connected to a length of hose. ?While it worked it was pretty slow to fill? balloon. I have since purchased 2 regulators from EBay, 1 single stage and 1? 2 stage. Both of them are the 450 series which has a high flow rate. Each regulator connected to a ball valve which connects to a common tee that has a hose running to the balloon. Using this setup we can connect to two tanks at a time and fill with one and have the second ready to go. Once the first is empty you turn the two ball valves and continue filling from the second tank. While the second tank is filling the balloon you move the 1st regulator to the third tank if needed. Using this setup we can fill a balloon to 20lbs of lift in 10-15 minutes vs. 20-30 minutes with the party balloon filler.

??

I use an oxygen regulator, got it at my gas supplier. Probably overkill, it's a two-stage regulator.

You could adapt a standard helium party balloon filler to the same purpose.? The main thing I like is a reading of the tank pressure, so I can approximate the volume of helium I'm using.? Knowing a standard T cylinder holds 290 cu ft at 2600 psi, you can work out the cubic footage vented by the pressure reduction.? The fitting are standard pipe fittings and you should easily be able to adapt to barbs for an oxygen fill hose.

You may be best off getting the party balloon filler on eBay (can be had for ~$30) and taking it to your gas or welding supplier and saying "I need fittings to adapt this to a length of oxygen hose".

I guess that all depends on what we mean by "we" ... ;-P. Assuming
you mean ARHAB, then EOSS has hauled up over 30 lb under a plastic
sounding balloon (U Colo "Humble" telescope on EOSS-6). Max load on
a 3000 latex was U Ky Big Blue, with a neck load of nearly 27 lb. EOSS
assisted Norm Kjome with a 250,000 cu ft ZPB flight of an 85 lb "Falconsat"
prototype from the USAFA in the 90's.

Earth air density drops roughly an order of magnitude (factor of 10) for
each 50K' of altitude. So getting to 150K' means that the balloon volume
must expand 1000 times greater than it was on the deck. The envelope
that you launch has got to contain that volume - so a bag that carries you
to 170K' gets pretty heavy, and you have to fill it with enough gas to
lift that envelope, plus any payload plus some to achieve a meaningful
ascent rate. The bulk of the gross weight is in the envelope, which is why
development of strong, light films is being pursued by folks like Aerostar.

It's great to learn that the unmanned altitude record of about 175K' set by
the USAF in the 60's has finally been effectively challenged!

Hi Pete,

A gas pressure regulator actually controls the pressure appearing at its outlet. In operation, a needle valve on the inlet side is controlled by a bellows connected to the output side. An adjustable spring loads the bellows to set the pressure. If the output pressure drops, the bellows opens the needle valve, and vice versa. The spring is adjusted using a multiple-turn knob, and it can take several turns to run the set pressure down to zero.

However, in order to get a decent level of flow thru any useful length of hose during fill, the pressure setting must be cranked up beyond the point that would burst a balloon neck in the event of torsion obstruction or pinch-off.

EOSS used to use a regulator on the tank, but it created more problems than it solved, in particular, by freezing up in a humid climate. So we just gone to controlling the flow using the tank valve, and keeping an eagle-eyed op on the valve to shut down if a twist develops. For multiple 3000 gm launches, we've got a manifold that lets us gang up two tanks into the fill hose, so that when the first bottle goes flat, we can continue the fill right away without moving fittings.

From: Jack <jscra@...>
Reply-To: Ballooning@yahoogroups.com
To: Ballooning@yahoogroups.com

Members of the Embry-Riddle Aeronautical University (ERAU) High Altitude Student Platform (HASP) team have been at NASA's Columbia Scientific Balloon Facility (CSBF) in Palestine, TX for the last week performing payload integration and thermal vacuum testing. Successful completion of T/V testing and RF compatibility testing was completed Friday, August 6, 2010 and ERAU received their Flight Certification.

Experiments aboard the ERAU payload include a gieger counter, and a light spectrum experiment built by Pima Community College, Tucson, AZ. The ERAU payload also contains power, communications, GPS, and data handling subsystems that will be the basis for potential satellite programs in the future.

The HASP platform flight is scheduled for early September 2010 from Ft. Sumner, NM depending on weather, etc. It will fly on an 11 million square foot zero pressure balloon with a target altitude of 120,000 feet. The flight duration will be nominally 16 hrs -- again depending on weather forecast, and flight path considerations.

The ERAU payload, Hatchling 1, will transmit standard APRS and payload data on 445.950 MHz once a minute. This data will be i-gated to the standard APRS internet server. More detailed schedule information will be posted prior to flight.

Additional information about the HASP program can be found at http://laspace.lsu.edu/hasp/index.html

Just finished working the W9YJ-11 balloon with great success. I started hearing the balloon at 26,497 feet at about 250 miles away. It wasn't strong enough to start hearing myself 'til it hit 30,391 with the first qso at 38,039. The best qso that should hold 6th place in the ARHAB records was with KD0FW. Distance of about 597 miles. KC8CUN also had a qso with KD0FW and that should hold 5th. We'll have to wait to get this confirmed. Great launch and Thanks for your efforts on the W9YF-11 launch.

8000. heaviest ARHAB payloads and waiver vs. notification

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-07 16:55:54 UTC
From: Mark Caviezel
Topic: 8000 Message: 8000

Paul:
I've launched three heavy payloads to date. One was a 40 pound phone booth sized (3'x3'x6') gondola, one was a 55 gallon polyethylene barrel partially filled with jettisonable brine ballast and the other was a NASA-funded payload about the size of a clothes washing machine. The last two were 152 pounds total payload each. The brine barrel flight was specifically intended to demonstrate and test an aggressively high stress level in my thin 0.75 mil LDPE balloon plastic. The phone booth flew under a Raven 9470 cubic foot balloon, the others flew under 10k cubic foot and 50k cubic foot Global Western zero pressure balloons. All of these flights reached a stable float with no problems. The NASA-funded payload was not an ARHAB flight (there were no amateur band emissions associated with this flight) but the others were.

Waiver versus Notification? For a number of reasons, the phone booth flight is likely the last time I will request a waiver, unless the planned flight truly can not be conducted within the published rules. The waiver for the phone booth gondola flight was handled extraordinarily poorly by the civil servants then. Indeed, I prefer to operate entirely within the Part 101 flight rules- no waiver, but with the required notifications and communication. Some ARHAB operators will mention that the radar reflector requirement is obsolete. Whether or not that is true, I will leave it to the FAA to set the rules. And when I am operating a flight, I will follow the rules; the required announcements and co-ordination are prudent and reasonable and not difficult to comply with.

I have run into similar waiver/notification issues when conducting Part 105 parachuting operations off-airport. I suspect because Part 101 and Part 105 operations are not in the day-to-day normal activities of many parts of the FAA, they try to guide/force this activity into a waiver process. As soon as you agree to get railroaded into the waiver process you set the stage for individualized local interpretation of national aviation rules. The goal of aviation safety is best served by uniform application of the federal rules.

best

Just a comment regarding Mark's comments relative to a COA (Waiver).

All but a few of EOSS's flights are exempt, so we can't often enjoy the freedom granted to those light flights.

1. The radar reflector is not required for exempt flights.

2. EOSS succumbed to the waiver requirement that imposed on us for the first Big Blue heavy flight by the now-retired FAA bureaucrat at Western Region; he demanded a waiver to 101.1 - the applicability clause, of all things, otherwise he's refuse permission to launch per 101.7.

So I went ahead and filed for that, plus the radar reflector and ceiling and visibility requirements as well - all of which were granted. Both were accompanied by technical justification based on the obsolescence of primary radar return tracking by the FAA and availability of GPS-based real-time tracking.

A successor at Region felt the 101.1 waiver bit was "BS" (her term), but the other two remain -and we've sure used 'em! This year alone, we've launched three thru solid overcast, and two were in 1/2 mile vis in rain. Those would have been scrubbed otherwise, and some 150 students would have returned home those weekends without experiencing flights.

The FAA can be a pain to work with from time to time, but they're amenable to reasonable negotiation where their demands go over the top. However, it makes no sense whatever to get crossways with them - they do have 101.7 at their disposal, and as a regulatory agency they can impose legal sanctions.

Regardless, EOSS defers the single-flight load record to ES-OS ; but I think EOSS has still hauled up much more total weight over its 155 flights to date.

I've rewritten the ARHAB.org web site so that all the support pages (announcements, members, records) are part of the menu system. If you get a few minutes, please take a look and let me know what else is needed or what is extra if that is the case.

I see the form to send me a flight announcement is missing, I'll add that right away. Anything else?

Thanks everyone.

Hi Keith,

Hey, that looks >really< nice. Well done, sir!

One suggestion: I use the "Members" page to find ARHAB groups which
may be located near someone who's looking for help. etc. Would it be
possible to add a column showing the 2-char state / province / country code,
and maybe some index of current activity?

Keep up the good work, man,

8004. Jet stream centering of neutrally buoyant balloons

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-09 16:14:06 UTC
From: dbowen1
Topic: 8004 Message: 8004

A curious question to think about...

In watching the Jet Stream forecasts for the trans-atlantic balloon flights, we were concerned at the narrow nature of the jet stream. It appeared that a balloon would have to be pretty lucky to stay in the middle of this fast lane of wind, many forecasts showed eddies along the edges and corners of the Jet Stream dumping the forecast track off into slow air.

We simply waited until the forecast track had us going all the way across the ocean, to determine when to launch, and tried to launch exactly into the stream where the prediction suggested. In the air, the balloons didn't seem to have a problem drifting horizontally out of the Jet Stream, until dropping out of it due to altitude loss.

I've been wondering if there may be some centering affect due to bernoulli's principle in the high speed air. The high speed zone should produce a lower air pressure- would this cause the balloon to stay in that fast lane of the stream (considering the balloon is at neutral buoyancy, and the fast lane is at the same altitude)?

Thanks,
Dan

Does that require the wind speed be different on opposite sides of the balloon or the balloon to have different curvatures on opposite sides?

Creating a differtence across a balloon may be difficult to create and then mantain.

There is a compnay that was planning to lower a vertical wing beneath a balloon. The balloon would actively maintain the oreintation of the wing and the wing would maintain a constant thrust on the balloon.

Paul

8006. BASE 48 and 49 at SpaceJam 4

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-09 19:54:14 UTC
From: BASE
Topic: 8006 Message: 8006

Dear friends,

Saturday's two flights were reasonably successful. Both flights were appreciated by the Scouts at SpaceJam 4 in Rantoul, Illinois. Landings were in crop fields (corn for 48 and soybeans for 49).

Thanks to Bill WB8ELK, the ATV on BASE 48 was received at least as far away as Michigan and Ohio. Ron N9QGS provided his APRS tracker and DominoEx for this flight. A problem in the SpaceJam ground station prevented us from getting any video recorded on site. Any images that anyone else obtained would be appreciated.

N8WAC already described some of the long-distance EBE contacts made with BASE 49. I wish we could have floated, the potential landing site was not balloon friendly. Instead, the extra altitude may have encouraged more long distance contacts. If anyone copied the DominoEx on 147.45 MHz for BASE 49, I'd like to hear from you.

One of the highlights for me was having Mark KA9SZX, Bill WB8ELK, and Al K9SI on the tracking and recovery teams (I know they've had a lot of fun together over the years). I also appreciate the recovery efforts of the Electric Eye team of Trey KC9QOV and Jay KC9QOW.

Additional details and photos are available from the website:

http://www.depauw.edu/acad/physics/base

BASE 50 should happen in September 2010. Exact date will be announced shortly.

Thanks again for your support,
Howard, KC9QBN

8007. Cost of ZPB's

Hi Dan,

Are you thinking of those dept store displays where a ball is suspended in space by some sort of vertical stream of air?

If so, then I thinkthe trick there requires an upward-flowing diverging cylindrical column of air, forming a low-drag bowl in the center - plus gravity. Can't think of common natural horizontal flows that could turn that trick, but I'm not a fluid dynamicist, either.

Hi Paul,

Since Aerostar won't sell to ARHAB, it's tough to get a quote. But I
think U Ky paid about $1500.00 for the 90K cuft bag we flew for 'em.
Mark NG0X might be a better source, since he rolls his own - and may know
of an offshore plastic source that's not run by risk managers.

Our Totex 3000's run us $260 each; $60 is more like a 1000 or 1200. Might
mention that launch expendables costs vary exponentially with neck load for
a given target burst height.

From: Mark Caviezel
Topic: 8010 Message: 8010

The current list price for the Global Western TA (Trans-Atlantic) balloon- identical to the SNOX 4 balloon- is $300. This model is specifically designed for long endurance, long distance flights. Larger displacements are available to qualified clients by custom quotation.

Despite rampant speculation on the internet discussion groups, the Global Western plastic is 100% made in the USA incorporating several modern technologies that you won't find on competing zero pressure balloons.

We're currently set up to handle balloon fabrication from 1 cubic foot to 10 million cubic feet. Our most recent balloon was 8.3 million cubic feet and is featured in the Space Dive cover story of this month's Popular Mechanics magazine.

best regards,

- Mark ng0x

ps I have one 'TA' in stock right now, interested persons can avoid the ten unit minimum order.

I just saw this story <http://www.kwwl.com/Global/story.asp?S=12955238> on the local noon news. It got my attention as ballons and explosion were mentioned. I'm curious to know the background and hope the injured wil be OK. Burns are never good.

See this:

http://www.press-citizen.com/article/20100810/NEWS01/100810003/UI-staff-member-injured-in-hydrogen-balloon-explosion

for a picture of the injured (photo taken months ago before incident)
and a very informative caption that may explain the general
task being undertaken which "required" the transport of inflated
balloons.

I hope that if the report was correct, that some of the balloons
were an oxygen/hydrogen mixture, they were at least quite small balloons. Easy to surmise why some of the balloons had that
2 gas mixture and some didn't.

Not a good idea to do that no matter how small the balloons.
Really bad idea, especially in a **totally closed** vehicle.
Fast or explosive combustion in a confined space equals
trouble. Even just a fire in a space like that is bad enough.

Hank

Joe,

Saw your post after I just did my first on this topic.

Why?

Ironically, to demonstrate to young people how pure hydrogen
just burns, while hydrogen with the proper amounts of air or
oxygen is explosive.

The whole thing is somewhat similar to the police officer
who, while conducting a gun safety course at a middle or high
school, shot himself in the foot at the front of the classroom
during the lecture with his police issued pistol.

That is a true story. It may be on youtube -- just about
everything is. I saw the footage maybe a year or two ago
on TV.

From the soundtrack it seems like it isn't the officer's own
gun, but one confiscated from a boy found playing with a gun.
It's a Glock 40. He's also a DEA agent technically.

Zack sent me all the PowerPoint and WebEx documentation from GPSL 2010, they are all now available for download at http://superlaunch.org.

Look in the right hand column under "Past GPSL Locations" for the link. Each file is available individually, so you don't have to download the entire 400Mg of files he sent to me.

I have not tested all the downloads, so if you run into a problem let me know.

73's

P.S.
The page is under construction, so if something else is amiss...forgive me please.

Hi Pete,

from the link:
--- clip ---
Director of Public Safety Chuck Green says a university staff member, Dale Stille, had loaded balloons - four filled with hydrogen and four filled with a hydrogen oxygen mix - into a university owned Ford Explorer for an educational event off campus.

When he opened the side door on the SUV, the balloons exploded.
--- clip ---

Probably just a little static discharge, or one of the balloons leaked and the dome light switch arced a bit. This goes to show just how little energy is required to ignite an H2-O2 mixture; far less than any hydrocarbon mixture.

Apparently these H2 party balloons were for some off-campus demo. The staffer probably was NOT the one giving the demo, however, unless he/she was suicidal.

Hydrogen has a huge flammable range 4% to 74% (or 75% according to this:
http://www.engineeringtoolbox.com/explosive-concentration-limits-d_423.html)
That's a big range.

You can see from the photo of the SUV that there was enough force to damage
the car.

It's a shame it had to happen, of course.

Not disputing static as a possibility, Mike. It's just hard to imagine that
with a local dew point temp in the mid 70s there would be a charge! Yuck!
I hate this weather!

8021. Inert gases in closed spaces

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-10 19:27:12 UTC
From: Mark Conner
Topic: 8021 Message: 8021

On my last trip to Linweld, the clerk advised me that they would no longer sell to customers who take their cylinders home in an enclosed vehicle. I normally use a small SUV (with two windows open) but I guess I'll have to borrow a pickup in the future.

Most of us on here knows the risks and how to mitigate them, but it's worth mentioning again that inert gases can kill too. If you do transport your cylinders in a closed vehicle, keep the windows open while the cylinders are inside even if unoccupied. Better yet, use an open truck bed or trailer. It would be a bad thing to get in a vehicle full of helium and not realize the lack of oxygen until after you began driving. Or if the leak began while driving and displaced the oxygen without you realizing it.

I was reading some safety tips about dealing with liquid nitrogen. One rule is never transport a dewar of liquid N2 on an elevator. If you spill it, you'll be unconscious or dead before the doors open as the nitrogen will boil and force all the fresh air out of the car. Probably not a useful bit of information for me, but certainly had never thought of it previously.

Also, with any high pressure cylinder, point the valve end towards the front of the vehicle so that should the neck fail, it's the guy behind you that gets killed, rather than you.

I agree he had to have a pretty leaky balloon!

We haved filled balloons with H2 and have a hard time to get them to
explode with an open flame.

And static, well you just need to know what to do and what not to do
when it comes to that and I agree it's tropical out there right now!

I've seen this classroom demo between a 100% H2 balloon and one
with about 15% O2 in H2. The pure H2 balloon goes kinda "whoosh" when
ignited, compared to a pronounced "BANG" for the mixture. Not like
Jim's acetylene, but plenty loud.

I suspect the bad address is because we're trying to remap the IP address of http://superlaunch.org. For now use the older, long link, it's still working.

http://nearspaceventures.com/gpsl2009/

Sorry for the confusion. Lots going on with our various web sites, but it'll settle down soon.

$300, thanks. Mark, I know you make ZPBs, are you associated with TA?

The $300 balloon, what is its volume?

So it sounds like someone can get into ZPB for less than I thought.

From: L. Paul Verhage
Topic: 8033 Message: 8033

Where can I find past flights? I looked at ARHAB.org and only found flight announcements for this year.

As I recall, we had over 200 registered flights last year. This year we have 133 so far. But I'd like to look at five years ago and see how many flights we had.

Also, I'd like to look at the increase in the number of groups. I counted 82 listed this year. But when I started in 1996, there must have only been around a dozen. Is there a way to check this?

Thanks.

Any news on the FDSL front?

We, in my humble opinion, should focus FDSL on amateur radio operators and public outreach.

We want to get more radio clubs to get involved in this exciting activity.

We want the public to know that they can design payloads that can explore a space like environment.

Once the public is excited by this prospect, they'll be more interested in working with their local clubs to get experiments launched. Who knows, they may even get a license and join a club.

8037. Promoting ARHAB and Consequences of growth in the hobby

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-11 12:58:30 UTC
From: Michael Willett
Topic: 3836 Message: 8037

Thinking out loud about the promotion of ARHAB at FD or in the news:

While I support expanding the hobby, I also fear the one person or group that causes a problem resulting in FAA rule changes, greatly impacting all of us and this hobby.

Right now, AHAB does not require an amateur radio license to fly a High Ball, nor does it require any training at all on preparation or safety, both for the balloonists or with a view of the FAA regulations in place to promote safety. In other words, other than a few FAA rules, there are no certifications required to get in the air to possibly cause trouble and ruin it for the rest of us.

Therefore, I feel a great amount of the efforts put forth now to promote our hobby should have a great focus on the "How to's" as well as a focus on safety, such as how not to cause the problems we all have seen. I personally have experienced the learning curve that I feel warrants a more laid-out plan for safe ballooning, such as how to determine your flight path, how to cut down the balloon, and a lot of this is beyond the initial understanding of the armchair enthused Joe Sixpack that would see the opportunity to send their camera to the edge of space and launches his balloon over the White House, Area 51 or class B airspace.

Much of our hobby (Amateur Radio) is self-regulated, and I personally would like to see our organizations unite to create an arm of our hobby with a focus on educating the prospective ARHABs to desire a "certification" of some type, even an on-line Q&A type of training guide to kick-start newbees into the hobby with a better clue about how, and consequences of what happens when things go wrong or are badly planned. At the end of the training, which I envision to be similar to the on-line ham radio training aids, where you see Q&As for testing for your technician license, you would receive a certification. This would help separate the Joe Sixpacks of the world from ARHAB individuals that take the hobby seriously and fly promoting safety and FAA cooperation.

Again, this is 7:30AM in the morning thinking out loud, but has been on my mind for some time.

All past flights are still there. In the upper left corner you will see a radio button titled "show all records" click that all all records currently in the database will show up. This goes back only to August of 2009 when I took over the record keeping.
Some day I hope to make it an actual query-able database but for now it is what it is.

8039. Announcements Database

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-11 13:28:21 UTC
From: Keith Kaiser
Topic: 8033 Message: 8039

Paul has asked a couple of good, interesting questions unfortunately I have not had the time to actually develop the announcements page into a real database. However it has a bunch of functionality which I have pointed out before but for those of you new on the list here goes.

1) Show All Records -- This radio button selection shows all the records in the data base from August of last year to current.
2) Show All Groups -- This button does a similar report but for the group you select only. It also limits the list to either the current displayed page or see #1 above to get the entire list.
3) Report! -- Way up in the upper left hand corner is what looks like a link, when click this produces a report of the complete database. Pay no attention to the last line in the report, I still need to de-bug that.
4) Launch Statistics -- On the right side of the banner is a basic stat report. Nuf said?
5) Help -- Please note the help link immediately under the ARHAB logo.
6) When I'm sent coordinates for the flight, I automatically build the links to Google maps, the various weather reports, etc.
7) When I'm sent a launch time and coordinates, I calculate the UTC sunrise time.
8) Any row listed in pink means it was cancelled for some reason. No reflection on the group, there are many reason to cancel.
9) Any row listed in green means there was APRS or other tracking available to look at.
10) Any row listed in white is yet to happen.

There are probably a few additional things I forgot but thats the bulk of it. I'm limited at the moment to using Javascript and CSS to build functionality. The server is not yet populated with PHP or Perl or even a SQL database and until it is, you have everything I can make happen, happen.

If you have any questions or idea, let me know please because I'm always interested in adding functionality.

The insurance is a plus I also admit,

But I bet we don't have the numbers to be able to get a good price.
Even tho we do have the facts of history of how to date not a single
claim would have been made. And what insurance company wouldn't like that!

Premiums paid and no claims paid out..

The other thing tho, is the possibility of a training program. or
something for all the new comers. With all the media lately since the
MIT guys came out, ever since there has been an awful lot of people
getting into this that have no clue at all that there are regulations.

I had one guy contact me with a flight he was working on, that was soo
illegal in soo many ways it wasn't even funny! I honestly can not even
remember what was all soo wrong, but there were like a dozen 101 rules
he would have broken if he flew what he was proposing.

Some sort of a mentoring program "Elmer" would be fantastic!

I know Bill ELK was my "Elmer" And without his help in my early days,
my first flights also probably would have been illegal also.

With our next flight I will highly video and document our filling
procedures we use when using H2. Well when we fill any balloon for that
matter because for all 50 flights so far all we have ever used is H2.
And our procedure is far different than what most would think.

73 all!

8044. Aug. 11, 1978: First Atlantic Balloon Crossing Takes Off

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-11 15:42:06 UTC
From: Keith Kaiser
Topic: 8044 Message: 8044

1978: Three Americans take off in a balloon from Presque Isle, Maine. They will land in a field north of Paris 137 hours, 6 minutes later, the first people to cross the Atlantic in a balloon.

After Lindbergh's famous 1927 flight, crossing the Atlantic in a balloon remained one of the last great unconquered aviation challenges. Ben Abruzzo and Maxie Anderson failed in 1977 at the 14th recorded attempt at a crossing. After their Double Eagle balloon crashed off the coast of Iceland, they were pulled from the gondola by a rescue helicopter. Though severely frostbitten, they certainly fared better than the five people who had perished in previous attempts.

From the wreckage of that failed flight came a successful crossing. Less than a year later, Abruzzo and Anderson were back in a gondola, this time joined by pilot Larry Newman. Like its predecessor, the Double Eagle II was built by legendary balloonist Ed Yost. Unlike its predecessor, the Double Eagle II had a crew with experience gleaned from its first failed attempt.

Hanging from the 160,000-cubic-foot helium balloon was a 15-foot-by-7-foot-by-4.5-foot gondola carrying the three men, a VHF radio, two single-sideband high-frequency radios, one automatic-direction-finder beacon transmitter, one maritime radio, a hookup to the Nimbus 6 satellite and a ham radio — which Newman used to relay messages after all the other radios stopped functioning.

Extreme temperature variations during the trip caused ice to build up on the outside of the balloon each night, with heat from the sun causing the helium to expand during the day. The balloon would rise and fall accordingly. This led to what the pilots called the "Big Drop" on Aug. 16: Double Eagle lowered to 4,000 feet because of atmospheric conditions and then rose to 24,000 feet the same afternoon after superheating from the sun.

The tower at Shannon Airport informed the crew on the night of Aug. 16 that the balloon had crossed into Irish airspace and successfully completed a trans-Atlantic crossing. The balloonists were invited to continue on to Le Bourget Airfield, where Lindbergh's flight landed 51 years earlier, but declined because they didn't want to risk an emergency landing in the heavily populated suburbs of Paris.

Instead of Le Bourget, the Double Eagle II crew settled for a barley field inMiserey, 60 miles north of Paris. The men were immediately swarmed by motorists from a nearby highway who happened to witness the historic touchdown. Newman slept that night in the same bed at the U.S .Embassy in Paris where Lindbergh had slept, and the entire crew was flown back to the United States on the Concorde, compliments of Air France.

Abruzzo, Anderson and Newman went back to the sky immediately to conquer more records. Tragically, Abruzzo and Anderson both died in aviation accidents, while Newman narrowly escaped death during a skydiving accident.

The gondola of the Double Eagle II sits today in the collection of theSmithsonian National Air and Space Museum. The general aviation facility near Abruzzo and Anderson's hometown of

Albuquerque, New Mexico, was renamed Double Eagle II Airport in honor of the crossing.

SigThe numbers wouldn't matter. If you want to pay for a club sanction it makes no difference if there is 1 or 1000 members under that sanction. I'm sure there are specific guidelines for a sanction, but I have not looked at the AMA rules.

We can't mentor all the lone wolfs that want to fly stuff into the sky. We can sure make an effort to do so. With all the attention HAB is getting there will be an influx of those that just launch with no understanding of the consequences. We really need a lot more media coverage to point out the risks and who to contact for mentors in geographic areas across the US. I would recommend that for every flight all, or as many as possible, local media be contacted and informed of the flight.

Paul
>>>>>>>>>> 'TA' is the model, short for 'Trans-Atlantic'. Volume is about 920 cubic feet.
http://global-western.com/Trans-Atlantic_Balloons.html
Yes, there seem to be a lot of unfounded wives' tales out there about zero pressure ballooning. Smaller plastic bag balloons (zero pressure and sounders) are not extremely difficult to fill and launch. The price point for the TA balloon is not too far off from one of the larger (2 kg, 3kg) latex balloons. The US Federal regulations do not restrict zero pressure balloons any more than they restrict latex balloon flights. Indeed, FAA Part 101 makes no mention of the balloon technology. As long as you are under the payload weights, ballistic coefficient, and other stipulations of the Part, no announcement, co-ordination, or waiver is required. Indeed, even if you are flying a payload of 13 pounds or more, 100% compliance with the regulations is not difficult.

best,

- Mark ng0x

Hi Paul,

The $40 per member annual dues mentioned at GPSL was a bit of a shocker. For a club with 40 or so members, like EOSS, that amounts to a pretty hefty annual sum - especially in light of the fact that it's the club, not individual members, who conduct the flights. Model airplane hobbyists each do their own thing, kind of like ham radio operators, so individual membership in AMA makes the same sense for modelers as ARRL membership does for hams.

There wasn't much discussion about liability insurance premiums, which seems to be AMA's most valuable offering to ARHAB, and only some passing mention of legislative / regulatory representation, which are the primary benefits which a national ARHAB organization might confer. And all that chest-pounding about their HQ building / staff / museum kind of gives a clue as to where all those membership dues go.

Wouldn't it would make a bit more sense for ARHAB to link up with ARRL than with AMA? At least both acronyms share a common term!

So IMHO, the quest for a national ARHAB organization continues, and it's looking like we may have to roll our own from the git-go, just like AMA and ARRL did.

Just the $0.02 from another voice crying in the wilderness ...

Mike, the "AR" in ARHAB stands for "Amateur Radio". We have granted an exception to our friends in the UK, which prohibits ham xmtrs on balloons (and other aircraft), but in the US, I think that a balloon group that doesn't fly with an FCC ham callsign aboard qualifies at best for "auxiliary" membership.

Hi Keith,

Man, doing a single database of ALL ARHAB flights dating back to Bill Brown's pioneering flight in '87 could a daunting task!

It might be simpler to provide a history page with links to existing club-generated web-based records, such as:

http://www.eoss.org/ansrecap/index.htm

IIRC, most of the ARHAB web sites that I've visited have their own flight history pages in some form or another.

Now, that wouldn't compile the ARHAB-wide total flight vs time that Paul wanted, but after one intensive pass thru the history pages could yield those numbers, and the current-year number could be updated fairly easily.

The only shortcoming of this approach is that it would skip flights by clubs that don't have web sites, as well as those which have gone belly-up.

Hi Harry,
Does that insurance come gratis with your annual membership dues?
And does it cover the unique risks associated with ARHAB (Class A
penetration w/o an IFR clearance, uncontrolled landing sites, etc)?

I did years ago, and IIRC, it would cover the club activities at the
launch site, but not beyond. Here's the latest dope:

http://www.arrl.org/affiliated-club-benefits

Click on "Club liability insurance".

Note that the coverage is pretty broad, but that premiums vary
depending on what the club does.

So ... maybe there's hope?

EOSS is an ARRL affiliated special service club. I'll nag the honchos
to pursue a quote based on what we do.

I an not sure we are on the same page. :) I know ARHAB is Amateur Radio, and I was not referring to memberships of any type... I was talking about separating uninformed Joe Sixpack from the rest of us that want to take a serious and considerate approach to the AHAB hobby, such as what EOSS and many of us do. To fly a High Ball, AHAB, etc, does not require one to be a licensed Amateur Radio Operator, Amateur Radio Operators are not even mentioned in FAR part 101. In fact, part 101 requires nothing of the operator other than to meet criteria of the aircraft capability itself. As a pilot, I find that a little odd, but the rules were likely written for another arm of the government (NOAA-like) and oh-by-the-way - the rest of us.

My concern is promoting the hobby may realize great success. And without education within that promotion, there is nothing to stop Joe Sixpack from flying without a hint of getting self-informed and giving us all a bad name (remember Balloon Boy) and resulting in eventual regulations that kills our Hobby or makes it a lot less fun due to strict regulations imposed by the FAA to alleviate the problems caused by Joe Sixpack.

I personally think it worth while to say "They were not "[voluntary self-certifying group] Certified" if there is a problem with an AHAB flying onto the White House lawn, or over area 51, etc. :) A highly promoted self certification (such as is used in most of Amateur Radio) would help promote a better approach to the AHAB or ARHAB hobby, help alleviate problems with new hobbyists and possibly provide relief from the FAA when an issue arises and some bureaucrat wants to knock us all out of the air.

An alternative way to generate a history would be to peruse Ralph's
announcements on the Balloon_Sked list archive. That would get you back a
few more years. Hank N1LTV might have some older stuff too from the 90s.

I personally think if something "big" happens, we're knocked out of the air regardless of organization. Our group isn't big enough in dollars, numbers, or anything else to save ourselves. The Government will exempt itself after a large amount of navel-gazing and imposition of an expensive procedural burden.

Not that there aren't other merits to a national A(R)HAB organization and some sort of certification as Michael mentioned, but this won't be one.

And just think of the mess that the HPR guys go through just to launch
to 2000 feet!

If I had to do what they do for every flight I'd probably stop.

My last AMA dues was $58 and my local club dues on top of that was $50.
There is a local club here that costs $200 a year, but they have a paved
runway and a club house with all the fixings, we don't.

Mike, I'm not sure about the specifics of the insurance coverage, but it is included with the annual dues, ONLY if I am flying from a sanctioned field. If I choose to fly from somewhere other than that, like a friends house in the country or out in the street here in the city, I think I'm on my own for liability!

73 Harry KC5TRB

Hi Harry,
Does that insurance come gratis with your annual membership dues?
And does it cover the unique risks associated with ARHAB (Class A
penetration w/o an IFR clearance, uncontrolled landing sites, etc)?

Goog info, thanks. As a side issue, I would be interested in a 24 hour balloon chase. Next year, I'd like to discuss this idea. Perhaps it could be a part of FDSL.

I lloked at Ralph's website and saw a mesage that his records were now at ARHAB. Perhaps I misunderstood something, but it looks like I can't find past records.

Can someone make a SWAG about the increase in number of flights over the last five years?

Paul

PS, Keith, do you want groups to start sending you a record of their flights? I can send them for NearSys (as KNSP and the shared flights with TVNSP).

From: L. Paul Verhage
Topic: 8035 Message: 8062

Okay, so it sounds like AMA is not really an option. I talked with Pat Kilroy about affliating with AMSAT but that got no where. So maybe ARRL would be an option. Thanks, Mike for rattling the cage about that.
I have no idea what it takes to create a ARHAB organization from scratch. However, something like that could cover clubs at an affordable price for the activity we do. I like the idea of a cert process before you can join and get insurance. It would also mean that someone irresponsible enough to violate the rules forfits their coverage.

Paul

8065. Re: [GPSL] AMA and a National Group

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-12 02:17:23 UTC
From: Pete Lilja
Topic: 8035 Message: 8065

There are two national organizations that deal with high power rocketry (another hobby of mine). The NAR <http://nar.org/> and Tripoli<http://tripoli.org/>offer members certification to 3 levels allowing people to fly various sized
high power motors to their cert. level. Providing the safety code for each organization is followed members are covered with $1 million in liability protection. These organizations are self-policing as well. The certification process is sequential through the 3 levels and one must be certified to purchase commercial motors through a vendor. This system works quite well. The second level requires a written test which can be found online much like the ham exams.

So, it seems to me it'd be possible to create a national organization, develop a safety code (or something similar for HAB activities) and have members show proficiency and understanding of that code and then get insurance to cover the liability from that activity.

But that's a lot of work. What is probably a more likely scenario is to create the organization as a place to develop and foster aspiring HABists. Be a place for those interested to come and learn about the 'How-tos' of HABing.

This is, of course, only my .02 worth... I have a personal liability policy with my homeowner's insurance that covers all of my (legal) activities.

And all that being said I know of two local rocketry clubs that have purchased their own liability policies that cover club members. I dunno what that costs nor how they did it but they did do it to to cover their activities that fall outside of the two national orgs. normal procedures.

8066. Past Flight Records

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-12 03:24:33 UTC
From: Keith Kaiser
Topic: 8066 Message: 8066

The only past records of flights that may exist are those trapped in old eMails. Ralph did not keep a database of flights, all his records were in 1 (one) very large Microsoft Word document. He would add a new flight, publish a new web page and send out the Word document to us all.

I have some of the old eMails with attached documents but certainly not all of them. I always thought it would be a great project to put all that into a database so I kept most of them. But I don't have the resources or the online database to make this happen at this time.

If someone needs a specific year, let me know off-line from the mailing list and I'll see if I can find what you need. I'm hoping others have old eMails too because I've only been doing ARHAB since 2005, and the oldest eMail I have from Ralph with flight announcements is dated November 17, 2005. But I will start a search in the online files that I have access to for anything older.

8067. RE: [GPSL] Past Flight Records

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-12 04:26:55 UTC
From: Rick von Glahn
Topic: 8066 Message: 8067

EOSS has a page that links to individual recaps from all our past flights. However, we also have a summary page that looks at all flights as a single set of data. That information is broken down in various ways but there is a spread sheet on that summary page that has all the raw data. You can discover things like...

EOSS has flown a total of 18,184.3 minutes in the air
Our average flight time is 121.4 minutes
Our max average ascent rate was 1710.7 fpm for the total ascent
We have ascended a total of 12,806,014.5 feet (yep 12 million)
Our average flight distance is 52.6 miles
Total miles flown is 7940.8 miles
We've lifted 1855 lbs.

If you download the spreadsheet you will probably become fascinated at some point. It is very interesting at times. But, word of warning, I didn't really start keeping complete records until Nick Hanks, N0LP came on board at EOSS and suggested I expand what I was tracking in the historical sense. So, that weight figure above is only a good figure for flights eoss-062 of 2002 forward. I didn't keep track of weight prior to that. There are other missing elements.

Oh, one other thing. This is a full on Excel spreadsheet (XLS) and uses VBA "macros" to calculate lots of the information, mainly distances and bearings. So, you'll get a macro warning when you load the spreadsheet.

Anyway, now that you're bored to tears... the spreadsheet basically gives total coverage of our efforts in this arena for the past 20 years.

I'm bringing this up because I'm kind of proud of our group's accomplishments but also cause, who knows, perhaps other folks have similar databases. Might be possible to concatenate a bunch of this into one record of what's been happening. On the other hand, probably not. Oh well...

Paul,

You are a member right now. I am an assistant moderator to
Rick.

> Could someone take a peak at 2005 and let me know how many
> announcements they see?

2005 message archive comprises about 250 separate emails.
Please do this task yourself since I don't think it can be
done with a "peek" if you're looking to see how many unique
flights or flight announcements were posted.

Hank

8070. History of independent, unified balloon launch announcements

Yes, Ralph Wallio is actually a newbie as far as independent, systematic posting of high altitude balloon flights go.

As far as I know, I originated the concept and practice dating at least as far back as April 1993 with Usenet postings, and then migrated that information to the massively used (1000 hits one day) central website for balloon launch notices (with a standard, uniform, *comprehensive* data format) called HABLIC (High Altitude Balloon Launch Information Center).

HABLIC operated for many years, but I eventually had to quit doing postings (for several reasons). I intended to revive HABLIC listings, but the final nail in the coffin was geocities discontinuing its free web hosting service. (I'm was totally aware that other free hosting was and is available, and in fact I use freehosting for other interests.)

Ralph adopted that concept and enhanced it with a parallel Yahoogroup email list.

Hank

Is there any archives of the old Pixar list?

> Are there any archives of the old Pixar list?

Joe,

That would be fun and informative to look over those for sure.
One list for all ballooning in the US.

Bruce would be the best bet to have created such an archive and
to ask. I kinda think if there ever was an archive, it's probably
not still in existence, but still worth asking about.

I think I can find an email for him.

How far below the package was the parachute in this video?
ARBONET-GPSL.wmv

I was amazed how unstable it was on the way up continually collapsing
on it'self.

I wonder if the slipstream from the balloon was causing it to collapse
like that?

What type of chute was it also? it did not seem to be a round chute.

Many of you may not know it but the http://superlaunch.org web site has been hosted on a number of different servers over the years. Bouncing from server to server depending on who was hosting GPSL that year. The last couple years I volunteered to maintain the site on the Near Space Ventures servers. That's why for example it always started out as <http://nearspaceventures.com/....>

Well effective today it has a permanent home. Thanks to Bill Brown who owns the superlaunch.org domain name and Troy Campbell who owns the servers it now has a permanent place to live. When you type in the URL you will see the URL in the address box. It will still take me a few days/weeks for me to finish the site and make it generic for GPSL. But I'm working on it, if you have any ideas as to what you want to see, let me know. But lets keep it off the mail list, send the idea to me...at wa0tjt@... that way the list stays for general discussion not web site specifics.

Thanks Bill, Thanks Troy this will make my life a little easier.

Yes, it was a round chute.

I think the balloon and chute were playing catch-up / slow down all the way up into the 60K+ area. The balloon would slow down due to the open chute and then the parachute would collapse, then the balloon would speed up and the parachute would open, cycle-after-cycle. Some was also likely due to the slip stream some due to the air movement needed to fill and open the chute. At higher altitudes the parachute becomes very ineffective, so it stayed collapsed more until it just stayed collapsed.

It was a 5' round chute, but one side was not tied up properly to the link.

The parachute was about 8-10' below the balloon.

I am not sure the text in the presentation captured the mention that I was up until 3AM working on gps firmware the day of the flight, and the video was a demonstration of two things: 1) Envelope pressure measurements realized and 2) How things really go very wrong when you are over tired and can't think. We went up there feeling pretty good, but the day of the flight everything that could go wrong, almost did.

8076. Tech Articles

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-13 16:12:14 UTC
From: Keith Kaiser
Topic: 8076 Message: 8076

I'd like to post more 'Science of HAB' stuff on our new arhab.org site. You can see whats there now, do you have any suggestions about more articles?

What's there now is the bulk of what Ralph Wallio left me when he retired. So please don't suggest I talk to him, but instead give me something new to work with.

You can send your ideas to either wa0tjt@... or arhabflights@... or even post them on one of these eMail servers if you want.

Keith,

It never hurts to have more good articles, and you and I
have talked about this in email before the makeover even took
place.

I would suggest moving

APRS Google Maps
On-line Balloon Track

to something like links, since they're not really science,
at least not science "articles."

> What's there now is the bulk of what Ralph Wallio left me when he
> retired.

It may be the bulk of what he left you, but it doesn't seem to be
the bulk of balloon related articles that he's put together.

One that is really useful is missing, and that's the GPS
characteristics table. You won't have to talk to Ralph to
acquire these, unless in the unlikely event he doesn't want
them posted elsewhere.

There are a couple others that are relevant, too. One looks
like it might have a numerical error in it. If it should turn
out to be in error, that should be corrected before posting.
I'll probably have Mike Manes look it over and see what he
thinks.

Hank

I don't have any flights scheduled to reach 100,000 feet. My balloons also
do not float, so they wouldn't stay up there that long.

I'm forwarding this message to the GPSL group. Does anyone here have a
flight scheduled or could they put together a flight to reach 100,000 feet
for 2 hours?.

If a lower altitude and shorter duration will work, I can help out.

If someone on GPSL can help out, please let me know. I'd like to help out
with the flight if it fits into my school schedule.

The system I shared at GPSL is designed to do just that, reach max altitude and float there for X amount of time.

It is not yet proven, but should be what they need.

How much weight in the payload? I have only logged the characteristics of a 1200 Gram balloon so far, I don't know what a 3000 gram balloon characteristic would look like.

8083. Happy 23rd anniversary for ARHAB flights in the US

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-15 23:53:36 UTC
From: wb8elk@aol.com
Topic: 8083 Message: 8083

Twenty three years ago I flew my first Balloonsat from Findlay, Ohio....why August 15th?....it was my birthday. As it turns out some of the pioneering balloon group founders that popped up after that also shared my birthday: Joe Mayenschein WB9SBD of NSS and Chuck Crist W9IH of Windtrax. I know there are others in the ARHAB community that share this birthday as well, so please post a message here if this is also your birthday. There must be something about this date that causes an interest in ballooning.

I do plan a big celebration of the upcoming 25th anniversary in 2012...any and all are welcome to join in a large superlaunch event on that date in Ohio.

- Bill WB8ELK

Yup

Joe WB9SBD & Near Space Sciences 1988 August something I don't remember
our actual date if it was on the birthday or not, but I know it was
august! Happy birthday to bill and the rest of us birthday boys today!

8092. Web Design

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-16 16:30:04 UTC
From: Keith Kaiser
Topic: 8092 Message: 8092

In web design one of the most difficult things to do is make sure your design works in the browsers your customers use. Todays web design is very robust, there are an incredible number of things I can do with just straight HTML, CSS and JavaScript. The problem arises in compatibility with each individual browser.

Moder browsers (IE >8, FireFox, Safari, Chrome) are easy to write for. But many people in the Windows world never move out of their less than capable Internet Explorer 6 environment. I would like to do some of the Web 2.0 type things in the various ARHAB.ORG pages, reports for example. But I'm concerned about our communities ability to use them if I do.

So I'm taking a little pole here to find out what browsers you are using. We are all high-tech kind of people so I hope I find the majority using modern browsers. But here is your chance to tell me otherwise.

What browser and version are you using?

Should I write for just modern browsers (see list above) or stick with the out of date?

Thanks....

As a web designer myself, I understand your dilemma, and have traditionally tended to stick with the older "lowest common denominator" mentality. Recently however, I've began to conclude that those who insist on running IE6 and the likes, are probably getting pretty used to sites not working correctly for them.

Move forward is my advice.

Latest Fire fox here, and I believe you can look at your ISP web server stats file to see what browsers and rev levels of those browsers have hit your site.

I think even win 98 (Mike M?) can run the latest browsers.

When you try to make something that is all things to all people, you never end up with anything as good as it could be. How's that quote go?... You can please some of the people all of the time and all of the people some of the time, but you will never make a liar out of Nixon.

Latest and greatest Firefox here as well as IE also. and like you also
several offbeat browsers too.

What I used to do when i was big into making pages I made mirror
versions. two complete seperate pages.

One fancy and state of the art and one basic.

Kinda like Broadband vs dilup, or HTML mail vs TXT only,

and the front door page of each had a link to the other.

worked pretty good a LOT of work tho.

an awesome way to see what using ur page is to use this one counter i
use. it's fast and really finds out a lot of stuff go to my clock page
and on the front page way at the bottom is the link to the counter

http://idle-tyme.com/

take the link to the counter and yoy can see all sorts of stuff, from
the browser status used. (Mozilla) is #1 (firefox) Ie 7 is in there
too as well as many many others.

One ting i find very nteresting and sometimes funny is the link that
says URL address <http://cqcounter.com/?sts,l20url,,,,IdleTyme>

That one shows what page people wee at just before coming to your page.
so you can see what in sending people to you or whatever.

sometimes it funny,, some people are really nasty! he he he pervs!
he he he anyway, that counter tells you a ton of stuff and it's free too.

I did a little digging and found this capture of the GPS vs altitude report from May 2007. It is a good starting place. I have no idea what was added after that date.

This is one of the very few pages I did not capture from Ralph's site. I found it to be so far out of date that I just couldn't justify it for the new site.

My bad!

If someone locates it, I'll spend the time to clean it up (no small task on his old pages) and post it on the new site.

Sorry guys!

I still have a lot of work to do on the 'report' pages. Getting them out of MS Word and reformatted for the real world is taking more time than I every dreamed it would. But progress as slow as it is, is moving forward.

I have the very latest version, dated by Ralph June 7, 2009.
Until very recently, there were links at the Wallio homepage
that pointed to the file at Ralph's site. The file itself is
still at the Wallio website, just at an undisclosed location:

http://showcase.netins.net/web/wallio/GPSrcvrsvs60kft.htm

I also have all the other balloon relevant Wallio articles that
I will email to Keith, with the exception of one that I believe
has a significant numerical error. I will endeavor to confirm
the error, rewrite the section with corrections, and then send
it to Keith.

KK> But the page is not optimized

Keith,

Optimized for what?

KK> and looks like....

Just what do you mean by "looks like ...." ?

Are you some kind of web page Rembrandt? :)

Looks fine to me (usually with Firefox), and a lot more
informative now that it's on arhab.org, compared to when
it wasn't on the page. Better to "look like ...." as you
say, and be on a website; then to not be on a website and be invisible.

You just said this,

KK> We are all high-tech kind of people ....

so I thought you got it that it's about content, first and
foremost. Style and cosmetics should be secondary to raw
content.

KK> I found it to be so far out of date that I just couldn't
KK> justify it for the new site.

This GPS information Ralph collected pertains to a range of a
GPS devices that spanned many years of production. It, of
necessity, has some observations that are more than a few
years old.

That doesn't mean it's outdated information or obsolete
information, just accurate information that pertains to older
devices, many of which are still being used and some of which
may even be readily available in the surplus market.

8112. Successful Zigbee telemetry from balloon to ground last weekend

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-17 08:20:46 UTC
From: wb8elk@aol.com
Topic: 8112 Message: 8112

I hitched a ride on the weekly Ozonesonde flight last Saturday to test out the final design of my Multi-Mode Transmitter and also attached a 100 milliwatt 915 MHz Zigbee XSC PRO module with a stock SMA rubber duck antenna. My MMT unit sent out the same telemetry string at 4800 baud to the Zigbee module (RF link was at 9600 baud) as was being sent down on DominoEx and 300 baud ASCII on 144.34 MHz.

Using an 8 dBi gain patch antenna on the ground with another Zigbee module mounted to the back of the patch antenna and hooked to my netbook via a USB interface, I was very pleased to copy quite a few transmissions directly from the balloon during the flight. The longest slant range distance was approximately 20 miles distance. I was even able to pull down some telemetry frames when the balloon was 19 miles directly above my house, which is right in the null zone off the end of the rubber duck antenna.

I was also able to copy a number of frames during the chase with the patch inside the car in the back window.

I was not able to receive anything using an omni gain antenna, so the 8 dBi patch would seem to be the minimum of what is required for this. I'm going to try a high-gain yagi in the next week or two and that should give me great copy on it as well as the ability to send commands up to the balloon.

I'm no Rembrandt but if I'm going to spend time on something, I want it to look and work good. You think the page looks OK, I'm glad, take a look at the 'source' and you'll see what I mean. You ask "optimized for what?" for maintenance, that's what.

It is a bear of a lot of work to fix the pages Ralph left in his wake. More power to him for being able to maintain such things but fixing them takes a lot of work and a lot of time. You might ask "fix what". Not a bad question except that to maintain a web page is usually far more work than creating it in the first place. In the case of Ralph all his pages were created with the absolutely, no one will argue, worst possible editor on earth for doing such things.....MS Word. It's easy to make a page using it, just save as HTML. But just you try and be a web master and maintain such a thing. That's why I give Ralph so much credit for what he did, it was a monster job and he did it for many years.

Well, I have a full time job, a large family, grandchildren, and my time is valuable to me. So while I love to be the web master, you'll have to give me the credit to work on these things as I see fit. Unless you might want to pay for a professional web developer. I may have called the importance of this GPS page wrong, but I'm now doing the best I can to get it back up and running for everyone. If it looks OK now it's because I took my time to go and fix it. It will look better when I have a chance to spend more time with it.

I appreciate all the kind words from the members of this list who have acknowledged my work on these pages. It will continue, and again if I missed something essential to your operation or just something that would make a good addition to the pages, please let me know. For those who are unhappy with my work, please let me know that too, I have plenty of work I can share with you to work on yourself.

> want it to look and work good. You think the page looks OK, I'm
> glad, take a look at the 'source' and you'll see what I mean.

Keith,

I may have needed to be clearer about exactly *what* looks okay and
what *looks okay* means.

I mean the exact unadulterated GPS html file, as created and still
present on the Wallio website, and as I have provided a link to on
GPSL before (GPSL message #8110, posted Monday), and will again now,
looks **perfectly good**, and as far as what any user of the ARHAB
website is concerned, needs no fixing by you or anyone else right now.

http://showcase.netins.net/web/wallio/GPSrcvrsvs60kft.htm

Whenever I refer to qualities of html files, I'm refering to
the "look and information content" from the user's point of view,
not what the source "looks" like or what qualities the source
may have as to maintainability or other desirable characteristics.

Your explanation of optimized was welcome and necessary because
I'm pretty sure a lot (maybe most) of GPSL subscribers did not know
what you meant by optimized. Thanks for clearing that vagueness up.

I have taken a look at your new, optimized html, remember this
is with regard to its rendering in appearance by the web browser
of an ARHAB website user, and to this casual viewer it **looks**
the **same**, no better, no worse.

Your optimized main html file is now bigger in bytes than it was
before optimization (101k vs. 93k), but if that increase gives better
maintainability, fine, it's only a small increase.

> So while I love to be the web master, you'll have to give me the
> credit to work on these things as I see fit.

I'm not sure that's the best policy with your limited time. I would
like you to pledge to not spend time fixing things that aren't broke,
particularly if you have family demands (see more about this below
when direct uploading of unlatered Wallio files is mentioned).

> Unless you might want to pay for a professional web developer.

That is entirely not necessary because you seem to be insisting on
doing things that don't really need doing.

> I may have called the importance of this GPS page wrong, but I'm
> now doing the best I can to get it back up and running for
> everyone.

All that was required was a simple upload of the GPS html file Ralph uploaded. That's it. If you want to create more work for yourself, I guess that's your choice.

"... GPS page ....get it back up and running for everyone."

Keith, please, this is not a complex process. You take a file and upload it. That's it. It's not a big deal.

You also said it R. Wallio's GPS file "looked like ...." Now I can be blunt, but I'd never say that on a forum about someone's excellent and meticulous work of compilation.

> If it looks OK now it's because I took my time to go and fix it.
> It will look better when I have a chance to spend more time with
> it.

It look okay now, because it looks identical to what it looked like before you worked on it. You didn't improve anything about its appearance as far as I can tell. Please don't spend any more time on making it look better because it looked fine as Ralph did it several years ago and it looks perfectly fine now.

> For those who are unhappy with my work, please let me know that
> too, I have plenty of work I can share with you to work on
> yourself.

I **very much appreciate** your willingness to do the ARHAB website, but I am unhappy with the way you're going about it as you can see, and I'm explaining my reasoning so you and all who read GPSL to understand why I feel that way.

I have several very **valuable** html files from Ralph that need absolutely NO modification when uploaded to ARHAB or any other website. I foresee no need for maintenance of any of these files.

I would request that you upload these files **as is**, and use the time you might have spent optimizing or otherwise modifying them to spend with your family.

> For those who are unhappy with my work, please let me know
> that too, I have plenty of work I can share with you to work
> on yourself.

As you know, through email to you over several months, I've been making suggestions about ARHAB content and form. I'm sure others have as well.

I think I could contribute to making technical information
getting posted more easily, efficiently, and accurately to ARHAB. So, I hereby volunteer to do some website work in that area, but I must be able to upload files, that are not broken, just as they are, and not be required to fix them when nothing needs to be fixed.

I could also serve as a technical editor of such files, calling
on other seasoned experts such as Mike Manes, Mark Conner, and
others to assist with that task as needed.

Hank

Bill,

It's always great to hear what you're doing and how it's
going (signal performance-wise).

I'm one of the few people who've used ASCII other than yourself.
I used much slower than 300 baud for better s/n. We use OOK
for ASCII -- what modulation mode did you use?

What was the performance of the other modes, and what powers/
antennas were used?

I have just received an email from Keith Kaiser which is kind of ludicrous -- it's his response to my email which I attempted to carefully and thoughtfully word so as to not create unwanted misunderstandings. I guess it still wasn't done well enough for Keith.

I think Keith at this point is not listening too carefully and taking this all too personally. I acknowledged some of Keith's valid points, and commended him on his willingness to take on the ARHAB.org project. I have no problem mixing approval and praise for a person in the same message as disagreement and constructive criticism. I'm not too sure about Keith, especially in view of this this latest email to me which he has chosen not to post to GPSL. (It's not what I would call off-the-wall, but kind of semi-irrelevant to what I'm trying to convey.)

The main point is that I will not split this thread between public and private. This is an important issue and it deserves to be discussed fully in a public forum, with no private outtakes.

So Keith, please either post to GPSL what you emailed to me (leaving out the 90k html source -- I and everyone else knows how to read source if they want to), or prepare a new, hopefully more rational response to the points I've raised and post that to GPSL.

Hank

Happy to oblige you Hank. Please find below the entire text of what I sent. Including the 90k file which is exactly the point I'm trying to make about maintaining this site. Be aware that the file in question is the GPS vs 60K Ft. report. But Hank, this is it. I will NOT justify you by responding to any additional comments from you. All others may send me whatever comments they wish, even criticism. --- Copy of my note to Hank starts here --- Off line this time. First I have made no changes to the file from Ralph... none, I have not "optimized" it for any use as of now. I simply changed the method of displaying it. I have however changed massively the files we use to report records. That process is now complete and I will take a look at the GPS file we have been discussing. In no way have I ever criticized Ralph's work, only the editor he used to do it. In fact I'm blown away by his work, always have been and will alway appreciate the efforts he put in. They were above and beyond, so don't reflect your feelings about him on me. Unless you are a webmaster, I really don't care if you think the file is OK or not. Maintenance of the file is far more important than its one time look. Below is the file source, look it over, tell me you would like to maintain this. When I'm done "optimizing" it I'll send you another copy and unless you're blind you'll see a massive difference especially in maintainability. To illustrate this, pretend you want to add a new row to the table, a new GPS has just come on the market, pretend to add its profile to this record below. I'm sure even you will agree that even finding where to appropriately add the new record is cumbersome. The file IS broke, even Ralph admitted as much, in fact it's one of the reasons he quit doing the updates. They were getting so much out of his control he didn't have the time or want to spend the time doing it any longer. I've spent more than 50 hours working on the arhab.org web site, another 10 on superlaunch.org. Constructive criticism is always welcome, criticism for the sake of criticism is not. W0RPK GPSv60KFT

GPS RECEIVERS vs 60KFT
Ralph Wallio, WÃ˜RPK W0RPK at netINS.net
Updated 07Jun09

The 60kft limit (aka 18km) is one of the three vehicle dynamics limitations placed on GPS receivers for we civilian unwashed, altitude, vehicle velocity and acceleration. GPS receiver manufacturers are allowed some leeway to juggle the values of these limits to serve their markets so details vary between manufacturers, between models from the same manufacturer and even between software versions in the same model. The 60kft (18km) upper limit of controlled airspace is the altitude limit most often used.

Amateur high altitude balloonists have discovered a few GPS receivers that allow operation above 60kft and often announce their findings to our small community. I have yet to hear of balloonists using expensive GPS simulators for this test so this knowledge results from actually flying receivers above 60kft and experiencing the results. This web page is intended to gather first person information submitted by individuals and groups that have tested receivers.

We will need to be picky about models, software versions and dates so submitted information will need to include:

Manufacturer
Model number (complete)
Software version (often output at power-up)
Individual or group involved in test
Date of test
Test result (Pass or fail)
Other relevant information

8120. Re: [GPSL] Re: Successful Zigbee telemetry from balloon to ground last weekend

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-17 22:43:37 UTC
From: wb8elk@aol.com
Topic: 8112 Message: 8120

Hi Hank,

For the 300 baud ASCII RTTY, I'm using 200 Hz audio tone shifts (1050 Hz and 1250 Hz) and 8N1 ASCII encoding. I use that audio to FM modulate my transmitter on 2 meters.

By using ASCII encoding of the RTTY, I can send down the full alphabet (upper and lower case with special characters) instead of trying to deal with ancient 5-bit Baudot. To decode it, I use the free soundcard program FLdigi and set it's RTTY mode to CUSTOM and set it up for the above specs. It copies perfectly at 300 baud almost down to the noise level, once you start hearing static noise, it doesn't work well, but the DominoEX still copies well. The ASCII RTTY is not as good as DominoEX22 in weak signal situations. DominoEX can give you perfect copy down to -10 dB below the noise level (even FM modulated DominoEX if you open the squelch). But as long as you have a good received signal, 300 baud ASCII really works great.

I've set up the tones on the ASCII RTTY to be the same as the ozonesonde....it sounds exactly the same. I made the ozonesonde folks jump last weekend when I turned on my transmitter since they thought they had accidently turned on their ozonesonde too early.

The folks at UKHAS have modified FLdigi to work with balloon telemetry that allows it to send the telemetry directly to their web server and display on a Google Map, provided you send your telemetry in the format that they need....their modified version is also a free download....search for "dl-FLdigi" to download the ARHAB version.

Currently I have my transmitter send one frame of DominoEX22 at the top of each minute, followed by two frames of 300 baud ASCII RTTY and then every 5 minutes, CW and Hellscreiber.

Bill,

It's always great to hear what you're doing and how it's going (signal performance-wise).

I'm one of the few people who've used ASCII other than yourself. I used much slower than 300 baud for better s/n. We use OOK for ASCII -- what modulation mode did you use?

What was the performance of the other modes, and what powers/ antennas were used?

Hank

Hank...just saw your other two questions....my output power last weekend on the DominoEX and 300 baud ASCII RTTY transmitter was 30 milliwatts and the antenna was a 1/4 wave whip....I bypassed the final amp and just ran it directly from my frequency synthesizer chip with some matching components....it pegged my S-meter using a 3 element Arrow beam on the ground during most of the flight....it was S-9 in the car as well.

Welcome to the world of Amateur Radio High Altitude Ballooning (ARHAB) Konstantinos. We would be honored to have you as members of our world wide group of enthusiasts and I have added you to our web site at http://arhab.org.

The best way to reach the most ARHAB members with your questions would be to join the two primary HAB Yahoo groups at;

http://groups.yahoo.com/group/gpsl/
http://groups.yahoo.com/group/balloon_sked/

On these mailing lists you will find the worlds leading HAB individuals and groups. They can answer any and all of your questions about any aspect of the hobby. Please join.

Many of our member groups have web sites of their own with project details going back 25 years, be sure to visit the members page at http://www.arhab.org/members/members.html and explore.

Thanks, Bill, for mentioning the antenna and especially power used.

That's a nice demonstration of what happens with a true line of sight path, and the performance can be extrapolated to orbit distances.

Balloon_Sked has been a YGroup for announcing flights for years and has remained pretty true to that topic. After Paul moved to Idaho, the KNSP YGroup became the general ARHAB discussion area. The GPSL YGroup has become like the KNSP YGroup and I for one liked it when it was limited to GPSL topics. That was it's purpose from inception and I would like to see it return to that. The description of the GPSL Group says... "This list is for the discussion of the annual Great Plains Super Launch, a gathering of amateur radio balloon enthusiasts. "

I remember about a moth ago everyone decided to not use the GPSL
reflector for casual non GPSL discussions.

But could be wrong.

8128. Re: [GPSL] Re: High Altitude Balooning and the GMG

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-18 21:35:28 UTC
From: Keith Kaiser
Topic: 8122 Message: 8128

The thing is, the obvious eMail address for us to use on Yahoo Groups would be ARHAB@... but thats the 'Ballooning' group over at ANSR. So unless we use that we'd have to come up with something new.

Lets just start asking people to use that, if they have no issue with it.

From: Mark Conner
Topic: 8122 Message: 8129

I have a draft proposal to the group that I'm still working on - basically, we rename the "GPSL" list to "ARHAB" (using arhab@yahoogroups.com which is not taken) and start a new GPSL-only list. The ARHAB group will "inherit" all the current "GPSL" subscriptions, archives, files, etc. I'll send it once I've worked out all the nuts and bolts.

I am relatively new to ARHAB, (joined ANSR '03; subscribed to "Ballooning" Yahoo!Group Jan04) and can remember "Ballooning" being used as a de facto general ARHAB discussion remailer. In the past, ANSR members have always been favorable to hosting any ARHAB traffic on the remailer/group. We are well aware that the 441 "Ballooning Group" members are not there to follow only ANSR endeavors.

If you decide against starting up yet another ARHAB remailer/group, and prefer to continue using "Ballooning" for general ARHAB discussion, then I'll revise the description page to reflect that it is open in that regard.

As to the ARHAB@... address, ANSR does not own arhab@yahoo.com or arhab@yahoogroups.com. Ours group address is

ballooning@yahoogroups.com

or you may message all five owners at:

Ballooning-owner@yahoogroups.com

Best regards,
James AC7ZT

8134. Balloon_sked needs to be brought back to its proper and rightful purpose

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-19 15:20:30 UTC
From: n1ltv
Topic: 8122 Message: 8134

> The best way to reach the most ARHAB members with your questions
> would be to join the two primary HAB Yahoo groups at;
>
> http://groups.yahoo.com/group/gpsl/
> http://groups.yahoo.com/group/balloon_sked/

I just noticed that balloon_sked is getting really
seriously cluttered with questions other than directly
related to scheduling.

Balloon_sked is the balloon group that is perhaps the
purest (maybe **was** purest is the correct wording) in
nature, and the one easiest to keep to its core mission
by moderator action that would encourage, or more strongly,
enforce adherence to its core mission.

As an assistant moderator to balloon_sked (with a low level
of involvement, up to now, other than with the routine
membership acceptance process), I would like to confer
with b_s moderator Rick about cutting down on off topic
discussions on b_s.

I certainly would not want b-s announced to be an appropriate
forum for questions other than sked related. Okay to find out
who's doing what, okay to pose scheduling questions, not
okay to discuss things like for instance the use of hydrogen
vs. helium.

I guess all of us have to start honoring the purpose of
balloon_sked, and there's no better time than now.

Hank

8135. Proposal: Rename/repurpose "GPSL" list to "ARHAB", create new GPSL list

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-19 15:45:13 UTC
From: Mark Conner
Topic: 8135 Message: 8135

Since we are now safely past GPSL 2010 and the recent discussion of the purposes of various ARHAB lists, I think now might be the time to throw this idea out to the list at large.....

The Yahoo Groups "GPSL" list started in 2002 as a list for just the discussion of the annual Great Plains Super Launch - the scheduling, logistics, frequency coordination, promotion, etc. For better or worse, it has also become an all-purpose amateur radio high altitude ballooning discussion list, with GPSL-related discussions ramping up in the summer and miscellaneous discussions continuing all year. This "all-purpose" mission has started to bleed over into other lists, including "Balloon_Sked" which was designed as an announcement-only list but has also started to drift.

I believe there is benefit in having a separate ARHAB general discussion list and one specific to the GPSL. There have got to be a large number of ARHAB enthusiasts out there who do not intend to participate in GPSL (even vicariously) and perhaps a small number who would like to participate in a particular year's GPSL discussion without having to sort through a large number of non-GPSL-related posts.

Having said that, the existing membership and archive on the current GPSL list would be difficult or impossible to migrate cleanly to a new ARHAB list. However, we can rename the "GPSL" list to "ARHAB" without any loss of the message archive, files, or subscription list. About the only change apparent to subscribers would be that new posts would arrive with [ARHAB] in the subject line instead of [GPSL]. The main page of the list would be modified to reflect the new name and purpose of the "ARHAB" list, and would be aligned branding-wise with the upgraded arhab.org website. This would hopefully make the ARHAB list more findable by newcomers and make it pop up higher when someone uses a search engine (I'm not sure anyone would find the GPSL Yahoo list by a web search, let alone understand its purpose had morphed over the last 2-3 years).

Here's the proposal:

1) Rename the "GPSL" Yahoo list to "ARHAB", keeping intact all the subscriptions, files, and message archives.
2) Redo the newly-renamed ARHAB Yahoo list's main page to reflect the new purpose, link to the arhab.org website. The arhab.org website could also promote this list as the "home" list for ARHAB discussions.
3) Create a new list for Great Plains Super Launch discussions, calling it "GPSL" if possible (not sure if the 'old' name gets released for reuse), or "SuperLaunch" if not.

This will require anyone interested in Super Launch discussions to subscribe to a new list. Posting of general ARHAB discusssions to the GPSL list will be discouraged, but periodic (not routine) GPSL updates will be OK on the ARHAB list. It is expected that the GPSL list will be quiet for much of the year - that's OK.

Balloon_Sked should also stay on its original purpose of announcing upcoming flights, including changes and cancellations. Routine discussions should be reserved for the "ARHAB" list or other group-specific lists.

I'd like to do this in the next week or so. Please post your thoughts on this list or e-mail me privately if you like.

Near Space Sciences Likes this.

But with one change.

Change the name of GPSL to ARHAB as discussed below. and keep everyone as a member a member.

Create the New GPSL list, but for now just take the complete e mail list from the existing GPSL list and add them there.

I bet there are far more people that want to be on BOTH lists than just one or the other.

In addition if someone does NOT want to be on one list or the other they can un subscribe from the one they don't like.

I thisnk this would be far simpler than having the several hundred re subscribe to a new one true?

Just sub everyone to both lists, and let them opt out of the ones they don't want to if any.

Cleaning up the lists is always a good thing in my opinion. In email I'm not sure it makes much difference but it does make it a lot easier if you want to look something up on the list archive site.

I would also suggest at least for the next few months you add a footer that lists all the lists and describes each list's purpose. A lot of incorrect posts come from not knowing where to actually post.

And finally, I suggest calling yahoo before you make the changes. My few experiences with their help desk have been reasonable and they may be able to do some of the changes in the background. My biggest concern would be the recycling of the GPSL name. They tend to lock old names for a while before allowing them to be reused.

Subject: [GPSL] Proposal: Rename/repurpose "GPSL" list to "ARHAB", create new GPSL list

Since we are now safely past GPSL 2010 and the recent discussion of the purposes of various ARHAB lists, I think now might be the time to throw this idea out to the list at large.....

The Yahoo Groups "GPSL" list started in 2002 as a list for just the discussion of the annual Great Plains Super Launch - the scheduling, logistics, frequency coordination, promotion, etc. For better or worse, it has also become an all-purpose amateur radio high altitude ballooning discussion list, with GPSL-related discussions ramping up in the summer and miscellaneous discussions continuing all year. This "all-purpose" mission has started to bleed over into other lists, including "Balloon_Sked" which was designed as an announcement-only list but has also started to drift.

I believe there is benefit in having a separate ARHAB general discussion list and one specific to the GPSL. There have got to be a large number of ARHAB enthusiasts out there who do not intend to participate in GPSL (even vicariously) and perhaps a small number who would like to participate in a particular year's GPSL discussion without having to sort through a large number of non-GPSL-related posts.

Having said that, the existing membership and archive on the current GPSL list would be difficult or impossible to migrate cleanly to a new ARHAB list.

However, we can rename the "GPSL" list to "ARHAB" without any loss of the message archive, files, or subscription list. About the only change apparent to subscribers would be that new posts would arrive with [ARHAB] in the subject line instead of [GPSL]. The main page of the list would be modified to reflect the new name and purpose of the "ARHAB" list, and would be aligned branding-wise with the upgraded arhab.org website. This would hopefully make the ARHAB list more findable by newcomers and make it pop up higher when someone uses a search engine (I'm not sure anyone would find the GPSL Yahoo list by a web search, let alone understand its purpose had morphed over the last 2-3 years).

Here's the proposal:

1) Rename the "GPSL" Yahoo list to "ARHAB", keeping intact all the subscriptions, files, and message archives.
2) Redo the newly-renamed ARHAB Yahoo list's main page to reflect the new purpose, link to the arhab.org website. The arhab.org website could also promote this list as the "home" list for ARHAB discussions.
3) Create a new list for Great Plains Super Launch discussions, calling it "GPSL" if possible (not sure if the 'old' name gets released for reuse), or "SuperLaunch" if not.

This will require anyone interested in Super Launch discussions to subscribe to a new list. Posting of general ARHAB discusssions to the GPSL list will be discouraged, but periodic (not routine) GPSL updates will be OK on the ARHAB list. It is expected that the GPSL list will be quiet for much of the year - that's OK.

Balloon_Sked should also stay on its original purpose of announcing upcoming flights, including changes and cancellations. Routine discussions should be reserved for the "ARHAB" list or other group-specific lists.

I'd like to do this in the next week or so. Please post your thoughts on this list or e-mail me privately if you like.

I agree this is the way to go, if it is possible. However, Yahoo by default makes it difficult or impossible to add people to a group without their consent (or spammers could use Yahoo as a delivery means).

Jerry had a good comment about working with Yahoo customer service on this to make it happen more smoothly which I'll investigate.

Keith:

I'd suggest a promenent link on the ARHAB.org site with something like "Beginner's Guide" (could be generic with info on everything from FAR101 to communications systems, etc) or "Community Guidelines" (more specific, with instructions on how to interact with each list). The folks over at www.diydrones.com have done a fairly good job of making their conops available to beginners from within the Ning architechture, I think, with links like that right at the top of the page.

Just a thought... I might be willing to help with content (not layout or design, sorry), but we'll have to see how my schedule works out.

In addition to a link on the ARHAB front page to the ARHAB list, I'd also suggest an arhab.org page containing subscription information and mission statements of any ARHAB lists people want to promote. The various list owners should be responsible for providing Keith this info, rather than him having to seek it out and writing it up.

Rather than changing GPSL to ARHAB....you might want to see if there is a way to just create ARHAB and copy the member list to that list.....just trying to avoid having to re-sign up to each list and losing folks that way....or it might be best to just create ARHAB and have everyone sign up to the new list (moderator invite?).

Renaming the GPSL list to ARHAB will automatically make existing "GPSL" members "ARHAB" members. The only signup required would be to the new GPSL list.

Much of the current message archive has more relevance to "ARHAB" than "GPSL", especially the last couple of years. I think that history more properly belongs to the new ARHAB list.

Yahoo Groups help says I can directly subscribe members to a new list, but only "some" at a time. You have to wait 24 hours or so to subscribe "some" more. It's possible Yahoo's help desk can help me "clone" the list, which would make things easier.

Thanks, Joe,

I also gave up on trying to find that on the G4tv site.

And yeah, its production values target the gamers, but if that's what it takes to get kids today to get involved, then so be it. And what little science that showed up was accurate, despite the format of its presentation.

Gotta give 'em credit for a 100% recovery rate (assuming that was their only flight).

8149. WB8ELK Oz25 flight from last weekend recovered

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-21 07:41:54 UTC
From: wb8elk@aol.com
Topic: 8149 Message: 8149

After a week of torrential rains, finally on Friday I had a good day to make the recovery attempt. Looked like it would be a "walk in park" since there was a well-maintained path/dirt road right up to the soy bean field where my experiment along with the Ozonesonde were resting.

After a 1500 foot hike I was thrilled to find a nice path around the edge of the soy bean field, so no need to hike 800 feet in waist high beans. Once I got to the nearest point, it would be a quick little jaunt of about 250 feet into the beans, grab the payload and head home....piece of cake.

It was that last 250 feet into the waist-high beans with an added nice touch of Morning Glory vines along with a heat index of 105 degrees that was the tough part....I also found out that a Garmin car GPS unit is not the best thing for tracking GPS coordinates on foot....somehow the waypoint on the Garmin got lost....I had remembered the Latitude, but couldn't remember the longitude (that bit of paper with the landing coordinates was back in my car a half mile away). So I walked along the latitude line to the west into the beans until I thought I had gone far enough....NOTHING....nothing but beans as far as the eye could see...no parachute flopping in the wind, no payloads covered with orange duct tape. It's not easy walking in soy beans that are drilled in solid....combined with the extreme heat it was miserable. I made a note of the longitude of my westernmost trek and since I didn't see anything figured that the farmer had found everything already and had already scooped it up.

I walked the half mile back to my car, drank a whole bottle of water and looked at my piece of paper with the landing coordinates.....to my chagrin, I had given up and turned around in the field 50 feet too soon!!!!!

Since I wouldn't have been able to sleep that night wondering if it really was still out there, I braved the heat and trekked the half mile back to the soy beans. This time, armed with both latitude and longitude, I hacked my way slowly to the exact spot....NOTHING but beans....I hiked another 50 feet west from that point and just when I was about to give up, I nearly tripped over a white string draped over the beans. I followed the string and there it was!!!! I had to be within 5 feet of it to actually see the payloads. I found the parachute and balloon all tangled up about 20 feet away, also invisible from more than 5 feet away...I wouldn't have been able to find either one without the string leading the way.

Everything is in good shape...(except me suffering from heat exhaustion). My bubble wrap enclosed payload was actually dry inside even after a week of torrential thunderstorms and still works just fine.

8150. Glitch with migration to "ARHAB" name

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-21 14:25:04 UTC
From: Mark Conner
Topic: 8150 Message: 8150

Well, shoot. I checked to see if the "ARHAB" name was taken by going to http://groups.yahoo.com/group/arhab and the Yahoo error page said there is no group called 'arhab'. So I thought all was good. However, Rick N0KKZ mentioned to me yesterday that he tried to create a group named 'arhab' several months ago and was unable to. I tried the same thing last night and was also unable to. It's possible that there exists an 'arhab' group but that it is unlisted.

I still have a ticket open with Yahoo about the migration, so I'll see what they say. In the meantime, we may want to think of alternate names for the group. We can still have "ARHAB" as a prominent search term for the group, but it might not be named "arhab@yahoogroups.com".

ARHAB is available on Google Groups. Actually, it WAS available - I went ahead and created it in case we want to switch over to using Google.

I've had good luck using Google for about a year with Project: Traveler, although my volume is so low that it hasn't been a good test...

Zack,
BASE_DePauw is a Facebook fan page that I use as a reflector for the Twitter account and as another place to post some videos and photos. I have a facebook account under the same name to control the fan page, and I have my own account to see what the fan page looks like to a 'fan.'
There is not much traffic on the fan page,but it is there.

Hi Zack,

Just taking a look at that myself, I added the video shown at GPSL this year to ARBONETVIDEOS on YouTube last night and was looking at an un-restricted Facebook page to use as a Blog. We have a web page named ARBONET.NET that needs updating (my ISP crashed and lost our web site), and a blog, but thought the three together, YouTube, FaceBook and a Web page may make for a really good set of tools.

Hey, I'd prefer a google group anyway, since yahoo's voluntarily pulled
email attachments off and required readers to pull up a browser and to
log in to see any attachment.

I've had good success with Google Groups, as well. I created one for our
local CERT membership, but like Zack it's pretty low usage.

Hi All,

Sorry for the mass mailing to all the groups here, But i guess hit them all till we get the lists all straightened out.

I'd like to contact the groups that fly multiple payloads on single flight strings.

Like I have sen maybe up to even a dozen small payloads and it does look like a train.

Any groups out there that fly these types of flights please drop me a line?

8160. Update on migration from "GPSL" to "ARHAB"

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-22 20:58:59 UTC
From: Mark Conner
Topic: 8160 Message: 8160

I got a response from Yahoo customer service earlier today. Most of the response was offering more specifics and restating their FAQ/help pages.

First, the Yahoo name "ARHAB" is indeed taken. We could get "AR_HAB" or "AR-HAB" though.

Second, if we rename "GPSL" to something else, the "GPSL" name would not be available again for 'weeks to months'.

Third, moderators can only invite 50 people per day to the list, or directly subscribe 10 per day. Obviously people could subscribe on their own with no rate limits. Yahoo offered no extra assistance in this area.

So we now have some choices, and I'm not sure which is the best.

1) Keep GPSL, start AR-HAB or AR_HAB at Yahoo
2) Keep GPSL, start ARHAB at Google (requires non-Google users to get a Google sign-in)
3) Rename GPSL to AR-HAB or AR_HAB, start SuperLaunch at Yahoo (possibly renaming it GPSL again when that name frees up in a few months)
4) Do nothing

I'm leaning towards #3 and calling it AR-HAB. The SuperLaunch name would also match superlaunch.org.

Please post your thoughts or send them direct to me if you prefer.

IMHO, "ARHAB" is entirely arcane enough for a newbie to find, so I'm 2-thumbs-down on "AR-HAB", >especially< in light of that fact that some other outfit already has "ARHAB" - talk about potential confusion!

The original discussion of a name change started, IIRC, with a minor gripe about how the original intent of the GPSL reflector having been besmirched by its having become more of a balloonacy techie forum than just a news site for a single annual event. That event, BTW, started out a just a mass launch, and has evolved to include a full-day conference, and, more recently, even another day of touristy stuff.

I personally have no problem with that evolution, but would favor a transition to another group dedicated to balloonacy tech ONLY if its group name bears some clear mnemonic connection to that field. Maybe that can happen with google-groups?

Otherwise, let's leave well enough alone (#4) and keep the GPSL reflector active year 'round.

8164. Re: [GPSL] Update on migration from "GPSL" to "ARHAB"

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-22 21:40:46 UTC
From: Joe
Topic: 8160 Message: 8164
Attachments: 1 described; binary payloads are missing from this source WARC

Is there a way, (through Yahoo support?) to contact who ever has the ARHAB, and find out what it is, and what it's being used for, and possibly if even if it's not being used at all even. I know of many groups that I have joined when they first appeared and thought it would be a good group to join, only to have it be me and the owner and no one else and not a posting in years! Maybe the current owner of ARHAB could give it up?

I wonder what it's all about even? Ya Know what can ARHAB stand for? When Googled it comesback mainly ballooning stuff

then a last name of people from the middle east, and finally an actual area of the middle east.

soo it really makes me wonder if some balloon group is the owner of it, but just forgot all about it?

or for that matter hey everyone. go to the page of yahoo groups where it lists all the ones you are a member of, (mine is currently 165 groups long) anyway go to it and make sure you are not already a member of this ARHAB group, or the owner for that matter!

I know I did just to make sure I was not the one that created it way back when and forgot all about it. (out of the 165 I did get reminded of groups I had made in the past for a purpose, but never did anything with them.)

Make sure one of our own already isn't a member or even owner of it!

Topic: 8160 Message: 8165

Maybe we should think about a new name instead of jumping on a variation of ARHAB right away. It makes sense if you know what it stands for but not when you first come across it. So to throw out a few names to get people thinking

HiBal - what FAA uses
HamBal - for Ham radio ballooning
HAB4AR - High altitude Balloons for Amateur Radio (maybe pronounce Hab-Far)
Balloonitics -Ive seen a few use this term

I kind of like true acronyms, ones you can pronounce.

Subject: [GPSL] Update on migration from "GPSL" to "ARHAB"

I got a response from Yahoo customer service earlier today. Most of the response was offering more specifics and restating their FAQ/help pages.

First, the Yahoo name "ARHAB" is indeed taken. We could get "AR_HAB" or "AR-HAB" though.

Second, if we rename "GPSL" to something else, the "GPSL" name would not be available again for 'weeks to months'.

Third, moderators can only invite 50 people per day to the list, or directly subscribe 10 per day. Obviously people could subscribe on their own with no rate limits. Yahoo offered no extra assistance in this area.

So we now have some choices, and I'm not sure which is the best.

1) Keep GPSL, start AR-HAB or AR_HAB at Yahoo
2) Keep GPSL, start ARHAB at Google (requires non-Google users to get a Google sign-in)
3) Rename GPSL to AR-HAB or AR_HAB, start SuperLaunch at Yahoo (possibly renaming it GPSL again when that name frees up in a few months)
4) Do nothing

I'm leaning towards #3 and calling it AR-HAB. The SuperLaunch name would also match superlaunch.org.

Please post your thoughts or send them direct to me if you prefer.

I agree with Mike, but I think Zack offered ARHAB up on the Google reflector system, having reserved it for this group just in case.

Since signing up with the AR_WhateverNewGroup may be a manual task anyway, I think looking at Zack's foresight to a Google group might be very worth while.

Personally I don't care if the group is on Google, Yahoo!, or any other site, it is a virtual world and should work pretty easy once you are signed up.

8170. Re: Update on migration from "GPSL" to "ARHAB"

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-23 02:43:14 UTC
From: Mark Conner
Topic: 8160 Message: 8170

I could be talked into option 2 (start the ARHAB list on Google Groups). I've already got both Google and Yahoo IDs so that isn't very difficult for me. I don't know how many on the list would need to have a Google ID just for this and would be reluctant to get one. Zack, can you directly subscribe members to a Google group or is it required to have a Google ID? If we can do direct subscription, the moderators could add a person to the list and they wouldn't need a Google ID.

Given the lack of assistance offered by Yahoo support with the migration of the list to a new name, I don't think they'll help us contact the Yahoo ARHAB list owner, nor help talk them into giving it up. Plus it would be the 'weeks or months' quoted me before the ID became available even if the current owner did delete it.

I'll be putting up a membership poll shortly so people can provide input even if they'd rather not do so publicly on the forum. The poll will be more advisory in nature rather than sealing the group's fate solely by the vote count.

Keep brainstorming and throwing out ideas!

73 de Mark N9XTN

8171. New poll for GPSL

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-23 02:52:53 UTC
From: GPSL@yahoogroups.com
Topic: 8171 Message: 8171

Enter your vote today! A new poll has been created for the
GPSL group:

The GPSL group was originally created to discuss the annual
Great Plains Super Launch, but now also discusses general
ARHAB topics. The question is whether to migrate the more
general discussions to a separate list and return GPSL to its
original purpose, or keep things as they are. The ARHAB
name is taken on Yahoo, but is available on Google. Also,
if we rename GPSL to AR-HAB, the GPSL list will not be
available for reuse for weeks or months.

o Keep GPSL, start AR-HAB on Yahoo
o Keep GPSL, start ARHAB at Google
o Rename GPSL to AR-HAB on Yahoo, start SuperLaunch on Yahoo
o Keep all discussions on GPSL, no new list

To vote, please visit the following web page:
http://groups.yahoo.com/group/GPSL/surveys?id=13030919

Note: Please do not reply to this message. Poll votes are
not collected via email. To vote, you must go to the Yahoo! Groups
web site listed above.

Thanks!

But see that wouldn't have to happen either. all the existing owner
would do is send invites to the person thats gonna take over and then
after they are signed up make them moderator.

BUT,

now I remember something in the back of my head that might be a
problem, If i remember correctly, once a group is made to be a private
or hidden group it can never be made open to the public again, maybe?

I think Jerry's idea has real merit. Variations of ARHAB, and
ARHAB itself are not as likely to guide people doing a websearch
as more obvious names would.

Does simple membership on a google reflector require signing up with google,
or is that just required to get to the group web site - like yahoo?

Rick N0KKZ ran an experiment and found that users can subscribe to a Google Groups list without a Google ID. One is required to work with the Google Groups website. So it appears it's a lot like Yahoo in that regard.

Paul,

Actually I think it is confusing how many list there already are.

And with all the activity showing on each, to a be comer they probably don't want all the email...
it would crash their inbox.

I think perhaps a forum would be the best to start for ARHAB or a wiki FAQ

something made newby friendly and Google searchable for many answer and discussions that keep coming up.

And let GPSL be open to all "NEW Questions and Concerns"

Carlton

I thought there was a wiki someplace,

and if it's a forum format NSS is gone.

I miss the weekly flight announcements that came via e mail.

Having to go to a web page to find stuff sucks OK I'm lazy. I would
rather hit the delete button 100 times deleting stuff that doesn't
interest me than have to dig through a forum to find anything that does
interest me.

The flow of information in a forum just doesn't work.

yup there is a wiki
http://en.wikipedia.org/wiki/Amateur_Radio_High_Altitude_Ballooning
Not a lot there but it's a start.

I'm a newbie here. I joined the GPSL to gain as much information on ballooning as possible. I don't launch but do try to work the balloons as much as possible. I also live in Ohio, Nowhere near the Great Plans so maybe my 2 cents worth doesn't count. This thread has gone on sooo long I can hardly remember how it started. I think it was about too much conversation on GPSL which was set up just for Graet Plans balloon launching announcements. If this isn't the case then just ignore this email. If this is the case, would it be better just to have a web site set up just like ARHAB Balloon Announcements? Then there wouldn't be hardly any posting at all here. From an outsider looking in....I also think it would be easier to hit the delete button than to go off and find the information that one is interested in. Again just my 2 cents worth from an outsider.

Enter your vote today! A new poll has been created for the
GPSL group:

The GPSL group was originally created to discuss the annual
Great Plains Super Launch, but now also discusses general
ARHAB topics. The question is whether to migrate the more
general discussions to a separate list and return GPSL to its
original purpose, or keep things as they are. The ARHAB
name is taken on Yahoo, but is available on Google. Also,
if we rename GPSL to AR-HAB, the GPSL list will not be
available for reuse for weeks or months.

o Keep GPSL, start AR-HAB on Yahoo
o Keep GPSL, start ARHAB at Google
o Rename GPSL to AR-HAB on Yahoo, start SuperLaunch on Yahoo
o Keep all discussions on GPSL, no new list

To vote, please visit the following web page:

8182. Scientist: World's helium being squandered

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-24 08:38:59 UTC
From: Greg Williams
Topic: 8182 Message: 8182

http://www.upi.com/Science_News/2010/08/23/Scientist-Worlds-helium-being-squandered/UPI-60551282600133/

As if they needed ANOTHER excuse to jack up the price of helium...

WASHINGTON, Aug. 23 (UPI) -- The world is running out of helium, a resource that cannot be renewed, and supplies could run out in 25 to 30 years, a U.S. researcher says.

Nobel-prize winning physicist Robert Richardson warns that the inert gas is being sold off far too cheaply -- so cheaply there is no incentive to recycle it -- and world supplies of the gas, a vital component of medical MRI scanners, spacecraft and rockets, could be gone in just decades, Britain's The Telegraph reported Monday.

About 80 per cent of the world's reserves are in the U.S. Southwest at the U.S. National Helium Reserve in Amarillo, Texas, but a recently passed law has ruled the reserve must be sold off by 2015 regardless of market price, Britain's Independent said.

"As a result of that act, helium is far too cheap and is not treated as a precious resource," Richardson says. "It's being squandered."

More of the story at the link up top.

Once a decision has been reached on a mail server, we can start making and recommending other changes to the way we work. Including but not limited to a weekly flight announcement eMail again. But first I think we need to figure out how to handle the eMail system(s) we have.

Fortunately, we in ARHAB do have a serviceable, albeit spookier, alternative lift gas: Hydrogen. Further, it's always been less expensive than He, and it's getting more so as the He reserve is depleted.

Now, it's also true that He is a byproduct from natural gas wells that's largely just vented. However, once the commodity price of He gets high enough, then it's likely that more natural gas suppliers will invest in the cryogenic processing necessary to recover the He product. Hopefully, that will occur before those for whom there is no alternative to He suffer too greatly.

ARHAB can help by getting cracking on developing and implementing methods for the safe and effective storage, transport and use of H2 for a fill gas.

It is with deap regret that I report the passing of Arlo Raim, KB9LLF. While I doubt that he aver tracked a balloon package, he was a legend in tracking birds with small transmitters aboard. Arlo probably had more experience in DFing than any 50 people combined, as he had been at it daily for more than 35 years. His old beat up Saturn station wagon with a big VHF Yagi on top was a familiar sight to us here in east central Illinois as he tracked his quary at all hours. Arlo also had the dubious distinction of being the cause of more calls to the sheriff's office in Champaign County than anyone in history.

Arlo was stuck by a freight train and killed instantly yesterday morning west of Chicago while plying his craft of DFing birds.

See http://www.chicagotribune.com/news/local/ct-met-bird-tracker-killed-0824-2010823,0,7368669.story .

Arlo's credit in wildlife research go back to the 1960's. He enjoyed an international reputation in avian research.

As one who has been involved with tracking and searching for balloon packages, and a sometimes avid foxhunter, I think this is a sobering story.

Al, K9SI

While we here at Near Space Sciences are up to flight 50, But it got me to thinking,

What group has had the most flights?

I'm thinking it's a race between EOSS with their 150+ flights, and or Bill Brown WB8ELK # of flights unknown.

So Bill, Denver,, who has had more flights?

Paul,

I hope you can compile a list of those 81 by location, date,
and perhaps at least a brief description of payload and
size balloon used.

That would make for good reading.

Hank

Attachments: 1 described; binary payloads are missing from this source WARC

Hi Joe....I will have to sit down and try to figure out just how many flights I've done or had payloads on....approximately 10 to 20 flights per year for 23 years....so approximately 300 to 400 flights to date but would guess it's closer to 400. Also have launched in 20 states so far as well.

It all depends on how you categorize things....I've flown a lot of payloads on other flight trains, particularly when I'm helping a group get started with their first flight or as part of university student flights, I've done quite a few of those kind of flights....also have done well over 20 ozonesonde hitchhiker flights, maybe more (can't resist a free ride as long as I keep my payload under 12 ounces). The payload weights I've flown has ranged from 2 ounces on up to 400 pound rockets....the largest balloon I've flown so far was a 512,000 cubic foot Aerostar zero pressure. Been flying about once a week lately. It's curious how the wind patterns can be the same from year to year. My Field Day balloon this year landed 400 feet from where my Field Day 2008 balloon landed. This week's payload landed 2 miles from where it did last week.

Subject: [GPSL] # Of Flights

While we here at Near Space Sciences are up to flight 50, But it got me to thinking,

What group has had the most flights?

I'm thinking it's a race between EOSS with their 150+ flights, and or Bill Brown WB8ELK # of flights unknown.

So Bill, Denver,, who has had more flights?

From: Mark Caviezel
Topic: 8196 Message: 8196

I love it when Nobel-prize winning scientist says things like "Helium is being sold too cheaply." If he truly believes that, he should start his own gas company and charge what he thinks is a good price. I'll predict his business demise if he charges far above the competitive market price. My advice to him: stick to the science.

- mark ng0x

ps and his info is bogus. I happen to know a man who maintains all the MRIs in a large western state. Helium conservation is a huge factor for how they run and maintain those machines because of the market price of helium.

8197. Helium Tank Threads

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-26 23:45:05 UTC
From: Pete Lilja
Topic: 8197 Message: 8197

Recently I had asked about regulators for helium tanks and it was suggested I purchase a balloon filler from an eBay seller. I did and it arrived today. The regulator / filler has a shaft with external threads and I seem to remember that the helium tank's valve also has external threads. Is my memory wrong or do I need to get a nut (union) for my regulator / filler?

I also remember that someone posted here (or on some Yahoo group) a McMaster Carr part number for a fitting that will fit on a hydrogen tank and allow the use of a helium-type regulator. I can't find it in a search of the groups' messages. Can anyone help with that?

Pete,
Helium tanks have internal threads on the valve. The valve head is CGA 580 (same as nitrogen).
Hydrogen is CGA 350.
If you want to use the helium regulator, you would need a CGA 350 to CGA 580 adapter.

==========

[GPSL] fill rates and Helium / Hydrogen Regulator

Helium / Hydrogen Regulator

There is a very simple and cost effective solution to converting to
H2 from He or changing between the two gases as required.

McMaster-Carr is your friend and with the following two parts and
some teflon tape you are in business for less than $10.

Part# 79215A666
Regulator Fitting Female Thread Inlet Nut, Cga #350, 0.950" Length
In stock at $3.47 Each

Part# 79215A667
Regulator Fitting Inlet Nipple, 1/4" NPT Male, Cga #350, 2.5" Length
In stock at $3.90 Each

And if you had a H2 regulator like I did they sell parts to let you
convert it to He which has worked just great for me.

Hope to see you all at GPSL.

RE Helium / Hydrogen Regulator
Posted by: "Nicholas Stich" NStich@... nstich48

Nicholas has it right: swap out the CGA 580 inert gas
nipple (and nut) for a CGA 350 flammable gas nipple
and nut. His McMaster-Carr reference is great, and
any welding shop worth the name will have these in
stock.

I used to work at a place that had over a dozen
different compressed gasses and we would swap CGA
nipples all the time. The whole point of 'the one
size fits only one' method is to prevent someone from

feeding an oxidizer into a flammable gas system, or an inert gas into a breathing air system. There is no reason to get a whole new regulator for a different gas (with the exception of Oxygen, which requires a properly cleaned regulator). Just make sure to be careful to avoid gas confusion.

The best way to make the swap is to grip to regulator body in a vise, then use a 6 point box end 11/16" wrench or deep socket to unscrew the nipple. Do not use an open ended wrench, DO NOT use an adjustable wrench, and heaven help us if you'd consider doing this with vise-grips or pliars. A normal 12-point wrench or socket is the only acceptable alternative. Unchuck the regulator body, and be sure to clean the teflon tape residue from the reg high pressure inlet before screwing in your new nipple (wrapped with teflon tape). Use of the less appropriate tools will significantly degrade the CGA nipple in question.

Personally, though, I take advice from the Navy Ballooning manual, and do not use a regulator. With cautious opening of the gas valve, the initial flow is modest. After the gas path is established (plastic balloon fill tube verified to be flowing without constriction) , we accelerate things a lot. On the ES-OS SEVEN flight (152 lb payload) we dumped a T-bottle (291 st cubic feet) every 30-40 seconds. As it turned out, a slower rate would have failed the mission as ten minutes after launch, a wind gust that certainly would have failed the balloon came out of no where. I was really glad we had filled fast and launched when we did.

California Near Space Project - High Altitude Attempt (K6RPT-14)

California Near Space Project (CNSP) is preparing to launch a high altitude balloon into the stratosphere on Monday August 30, 2010 at 5:00 a.m.

The launch will take place at 4954 Almaden Expressway - San Jose, CA 95118 (37.25945 -121.87479)

The weather balloon will be filled with a 137 cubic feet of helium to a diameter of 6.4 feet and will ascend around 730 feet per minute. When the balloon reaches its maximum altitude it will expand to a diameter of 42 feet and then burst.

What's interesting is that the ascent rate has really dropped off in the
last several minutes, to less than 150 ft/min. Suppose it might float?

California Near Space Project - High Altitude Attempt (K6RPT-14)

California Near Space Project (CNSP) is preparing to launch a high altitude balloon into the stratosphere on Monday August 30, 2010 at 5:00 a.m.

The launch will take place at 4954 Almaden Expressway - San Jose, CA 95118 (37.25945 -121.87479)

The weather balloon will be filled with a 137 cubic feet of helium to a diameter of 6.4 feet and will ascend around 730 feet per minute. When the balloon reaches its maximum altitude it will expand to a diameter of 42 feet and then burst.

California Near Space Project - High Altitude Attempt (K6RPT-14)

California Near Space Project (CNSP) is preparing to launch a high altitude balloon into the stratosphere on Monday August 30, 2010 at 5:00 a.m.

The launch will take place at 4954 Almaden Expressway - San Jose, CA 95118 (37.25945 -121.87479)

The weather balloon will be filled with a 137 cubic feet of helium to a diameter of 6.4 feet and will ascend around 730 feet per minute. When the balloon reaches its maximum altitude it will expand to a diameter of 42 feet and then burst.

It looks like the chase crew has left the site (N3CKF-9 and KO6YQ), but the payload is still beaconing from where it landed. It's in a forested area, so maybe it's way up in a tree.

The K6RPT-14 flight went well today reaching 122,649 feet. After the flight I had to go back to work.

CNSP did not plan to recover this payload. Another group's chase and recovery team, with one team member in an airplane went after it anyway. They said the terrain was difficult for recovery.

I was surprised how slow it was ascending at the end of the flight? I thought we had a floater at 122k.

Ron,
Did you transmit any temperature data from your system?
The density of the stratosphere at 37 km ASL is very small, making the density difference with the helium smaller than what might be assumed via LiftWin.
Howard

I didn't do any temperature logging my payload was already about 5 oz too heavy already.

Thanks Howard, Understanding the density of the stratosphere at 37 km ASL and helium will help in my next attempt.

8220. Does anyone have any information on the balloon launch of Project Electric Eye?

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-31 18:40:02 UTC
From: Mike Bogard
Topic: 8220 Message: 8220

I can not find out any information of the flight tomorrow of the Project Electric Eye. If anyone has any information on the flight or link to where the information is I would be interested in seeing it. Thanks Mike

8221. CNSP (K6RPT-14) flight ascent profile

Yahoo group: GPSL (2009 — 2010)
Date: 2010-08-31 18:56:06 UTC
From: BASE
Topic: 8221 Message: 8221
Attachments: 1 described; binary payloads are missing from this source WARC

I plotted the ascent profile for Ron's flight (see attached .jpg) from the aprs.fi raw data packets. Something very interesting started to happen after about 2 hours and 15 minutes.

Any explanations?

Howard

I didn't do any temperature logging my payload was already about 5 oz too heavy already.

Thanks Howard, Understanding the density of the stratosphere at 37 km ASL and helium will help in my next attempt.

The flight information for Electric Eye 8 can be found on the following link:

http://www.arhab.org/ARHABlaunchannouncements.html

Launch is scheduled for 8:45 am Eastern Daylight Time from Riverton Parke Junior-Senior High School in far western Indiana (Lat/Lon: 39.698,-87.32)

Call sign: KC9QOV-3 on 144.39 MHz APRS using a 1500 gram balloon with hydrogen.

I could not reach the flight list from the www.arhab.org home page, but had to enter the URL directly.

Thanks for the information but I don't seem to be able to see what the payload is? I am trying to find out if it is live video and if so are they transmitting it on a ATV frequency or just what are they doing. There is just a lot of missing information on the ARHAB announcement site from the Electric Eye Group. Thanks Mike

From: n1ltv
Topic: 8220 Message: 8226

> Everything the Electric Eye Group sent me regarding their flight is
> posted.

Keith,

You have several events on the launch page, including Electric Eye, where no town is listed, even some where no state is listed.

Please try to **always** list at least the state without someone having to guess it from looking up a webpage link. Sometimes the launch state is different than the home state location, so it should be spelled out.

A special building name, an airport name, or a school name is a royal pain in the butt to decode for us civilians out here looking for the critical information. It's not acceptable for a good launch announcement webpage to just have those kinds of descriptions (the three above) that need much further decoding.

On the HABLIC website, the launch info was always fitted into a pretty standard (with custom addons where necessary) format, and one of those items was a *specific, complete* launch site as town, state, and if a very small town, range and azimuth to a bigger town or city in the state. If those descriptors were not provided by the launch teams, I as HABLIC webmaster, looked them up so others would not have to.

In the case of range and distance to a well known town or city, I always had to do it.

Hank

> Any explanations?

A "pinhole" leak or other small leak, perhaps at the neck
foldover point. Developing logically late in the flight
from the extreme envelope expansion.

Hank

Hank,

You know what, your criticism of everything is really getting the rest of us down.

If you don't like things the way they are why don't you do it yourself? Go start your own site, lets see how many others actually join you.

I post what I'm sent, I don't make things up, I do embellish by adding links to places I think will help, but based on what I'm given. I'm not about to start making up data just to make you happy. If I'm sent specific location information, I post it, I post everything I'm sent, I don't edit. Now if you would care to write a geocoding program in JavaScript that will go to one of many sites around the web and return the City and State of the launch coordinates, I'd be happy to include that in my "embellishment".

Try contributing to things Hank not detracting. I for one am very tired of it.

Hi Howard,

I also noted the leveling off at around 121,000 feet. It got my attention too. Knowing that burst happened shortly after, I would say it had a pre-burst hole that slowed the ascent rate, but not enough to over come the continued ascent to critical pressure and obtaining burst. "Captain, she can't take any more" "Give me all you've got Scotty" then blamo... :)

The other possibility I thought of was an area of sinking air. Though air is thin up there, it still moves around, and I have encountered very large areas of sinking air when flying a plane, I can imagine those areas also exist at high altitudes.

However, my money is on the pin hole as it nearly matches the profile I expect from using the valve system and likely matches that of Bill Brown's pin-hole experiments.

This seems to happen more frequently than not for 3000g balloons, sub-1lb payloads, and flights to the 120 kft vicinity. Or maybe it's selective memory on my part. Does anyone recall a "normal" flight under these payload/balloon conditions, where there was not a substantial leveling off of the ascent rate before the burst altitude?

I find it a little hard to believe that we get pinholes this frequently.

Can anyone give me some exact spec's on this flight.

I know it was a 3000 balloon, but little more.

Like Gas used,

Total exact as possible amount of lift at the nozzle. NOT any other spec, But the total amount of lift, and then the exact payloads flight train lift too.

In other words then to be able to calculate the total amount of positive buoyant lift of the whole system.

I'm thinking myself that with the minimal lift, and the extra rarefied atmosphere, I'm wondering if we had a close,, but not quite good enough Pressurization of the envelope. and the lift was reduced, but not canceled. The envelope wasn't strong enough to pressurize enough. To totally cancel the lift But it did reduce it.

What I'm thinking is at 120 K point was where the envelope has hit that cant stretch any more point, And now the pressure differential starts to rise. But i need accurate numbers to calculate these numbers to see what the actual pressure differential would have had to be to act like this.

Joe, this is what I used form LiftWin. I used a hanging scale (upside down) and the nozzle lift was 2.38 exactly.

3000g HE, Total Payload .75, Nozzle Lift 2.38, Free Lift 1.63, Time to Burst 3.0, Ascent Speed 730, Estimated Peak Altitude 133K

The standard air pressure at 121,000 feet (37,000 meters) is 0.063 PSI. I would think at that point I would think that the slight increase in pressure caused by the balloon would have to be taken into account.

How close does the scale work "Up side Down"?

Just curious as to it's internal workings, if what it says the lift was
is really what it was.

And how to test it?

Maybe with a balance beam? make a balance beam with exactly the same
weight (Preferrably 2.38 pounds on both ends so it balances exactly,

The remove one weight and attach the scale as you did to the balloon and
confirm that it says you have the same for the lift.

Was te balloon inflated inside or outside? any breeezes etc. all
effect what the true amount of lift was.

I'm still not sure I buy the pressurization theory - I just can't see latex stretched that thin suddenly exhibiting a lot more strength. I don't believe we see this with, say, 1500g balloons at around 100 kft.

A pinhole, with a minimal pressure differential behind it, wouldn't seem to vent a lot of helium in an hour or two. I suppose one could do the math using a minimal but hopefully realistic pressure differential through a hole of various sizes and see just how long it would take, but we are probably talking several hundred to a couple thousand cubic feet at least.

I wonder if we have something like the Reynolds number transition that's observed at other altitudes with smaller balloons - maybe we get into a flow regime that introduces a *lot* more drag. Or maybe a change in the balloon shape (more oblate?) that causes the drag to change due to the balloon's manufacturing and different thicknesses of the latex at different points around the surface.

It would be interesting to collect the data for all 3000g balloon flights exceeding, say, 115 kft with light payloads and relatively low free lift to look for some commonality. I still remember chasing Pete Sias' January 2000 flight that went from Salina to Ohio, and use it all the time as an example of a "weird" flight.

There isn't a whole mess of experience in ARHAB above 120K' - this is
the darker side of an already black art :=P. I kinda suspect a dive
off the Cliffs of Reynolds (per Nick N0LP) may have played a hand, although
I've never seen such a large Re-induced inflection.

Somebody and I don't remember who presented at GPSL this year about the pressure increase in a balloon just before burst. I found some stuff on party balloons describing this effect but nothing on weather balloons.

A few ounces of extra pressure at lower altitudes is going to wash out in the noise but at 120K feet where the outside pressure is 0.06 PSI it could make a big difference.

Huh? At a given temp and pressure, the density difference is still a firm
function of the difference in molecular weight over the fill gas mass,
independent of absolute pressure.

There was a BOI flight back in 1999 that fit that profile.

I try to fly with 3 PPL. I susppose the sub-pound payloads need to look at
flight termination devices. That way you know you won't be up there when
the batteries die.

I think Howard is saying the difference in density (pressure)* as you change altitude is smaller at 120,000 feet.

Boyancy depends on being less dense than the medium you are immersed in.

Does a change in density per foot affect ascent rates?

Paul

* There's a 1% difference in pressure and density at 100,000 feet than at sea level. By coincidence, the accleration due to gravity is 1% less at 100,000 feet. Perhaps this makes sense, since pressure is a force and force depends on mass (related to density) and the acceleration due to gravity.

That presentation was by K5NOT - from ARBONET. The phenomenon of a pressure increase before burst is documented by ARBONET and the University of Minnesota, it is really there. I am not sure that it would result in the decrease in envelope expansion enough to demonstrate the near neutral buoyancy of the K6RPT-14 flight. But yes, the latex does start resisting continued expansion at the point I call "mechanical maximum" - where the latex just can not stretch anymore before tearing. Under ideal conditions, the lack of increased displacement of the envelope due to reaching the mechanical maximum would result in a floater, since the balloon envelope would start compressing the helium, possibly enough to achieve a balance between displacement and compression, thereby resulting in reduced lift. This is a very fine line though. We don't normally see this with 1000'ft/minute ascent rates, but at very low ascent rates like the K6RPT-14 balloon, this profile absolutely could be an indication that mechanical maximum was reached, the envelope resisted further expansion due to the lower initial envelope pressure, the very sparse helium mass started to compress, and the ascent started to level off. However, in this case, ascent was never fully arrested and the mechanical maximum was exceeded, resulting in an envelope failure.

Just one thought among many viable explanations...

We will never really know, since we don't have a profile of the K6RPT-14 envelope pressure, and no concrete evidence is available to dispute any sound idea about what happened up there.

I can not seem to find this answer,

Does anyone know what gas was used?

was it HE or H2?

Joe, I test tested the scale before the flight and I did the fill indoors. I put a couple of pictures on the website for you to look at. The Gas was HE.

In the GPSL presentation where you flew the differential pressure sensor.

I Know the numbers on the chart are meaningless.

BUT,

can you give me the altitudes that the payload was at at various times
during the flight?

As many as possible would be best. But at least what altitude it was at
for at least these three levels.

135 Min into the flight.

165 min into the flight,

and 195 min into the flight.

any others would be cool too.

But what altitudes for at least those three.

Thanks A Lot.

Just a clarifying point. The numbers in the ARBONET data are/were not meaningless. The scale is simply arbitrary and therefore the numbers lack units (pascals or p.s.i or ...). The numbers hopefully have relative meaning, especially if the sensor response curve is well known.

Yeah,

That is actually more accurate description. I was just using the verbiage that was in the presentation. If i remember it correctly. But even that could be wrong.

You are right Howard, the numbers demonstrate the relative pressure throughout the flight. The sensor itself is pretty linear, we stayed within or near the temp specs of the unit, and I won't say the unit is perfect, but I think the contribution of the offsets due to temperature would not be super significant.

Joe, the data in the presentation is all I have. Our GPS was not behaving well, so the altitudes past 29,000 feet were not reported. The altitude values received are shown in a graph within the presentation.

I am not sure I used the word "meaningless", but rather "not calibrated". I would hope I would not waste everyone's time presenting "Meaningless" data. If I did do that, I would be either a lawyer or very successful in politics! :)

Afternoon Michael,

If it was taken as a misunderstanding I apologize. Maybe it was someone in the chat room that made the comment about meaningless. And it stuck. Again Sorry.

So looking through the presentation again, I'm guessing a time of burst being about 195 minutes into the flight correct?

And an Bill ELK max altitude estimation of 110,000 feet.

if thats the case then I get an average of about 560 feet a minute rate of climb correct?

Yes? No?

8256. K6RPT-14 payload found

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-01 16:22:07 UTC
From: k6rpt
Topic: 8256 Message: 8256

I just received an email from the property owner of where the flight went down, he has found K6RPT-14 payload. (Copy of email below)

-Ron K6RPT

Mr. Meadows,

Yesterday, Aug 30, Joe Pistritto and Ian Kluft pulled up in my yard and told me they were looking for a bolloon. I pointed the coordinates they gave me into my Global Mapper program with an overlay of the USGS Topo for this area. I knew then we were in for a hike. After hiking the woods with Ian's GPS we gave up - the tree canopy was too dense to allow an accurate reading.

Today I decided to try again. Armed with a waypoint in my GPS, I took an easier route to within two-tenths of a mile of the waypoint. An hour of hiking back and forth (mostly up and down) made me realize that following a bearing arrow was fruitless. At one point I even had to find a clearing and reboot my GPS. Then I started reading my current coordinates and comparing them to those of the waypoint. Bingo.

What's left of the balloon and the two white payload boxes attached with red cord are about 40ft off the ground in a Madrone tree that grows almost horizontally out from a 45 degree bank. Knowing well how brittle these madrones are, I fought off the inclination to shinny 40ft or so out this tree. But the good news is I know where it is.

No, no offense taken, no harm done. Joe I may have well said meaningless - referring to the scale shown on the left side of the graph, and instead meaning "relative or not calibrated". I said a few things in my presentation that made me desire a rewind button on my forehead, but that button did not seem to work when needed. :)

The balloon was inflated for a standard ascent rate, something like 1.6 X weight, but the parachute was deployed as a drag chute unintentionally and we ended up with a slow initial descent rate. However, the ascent rate greatly increased as the parachute was less effective at altitude and realized more of the slip stream as the balloon diameter increased. If you watch the video you will see the parachute hanging limp near burst, yet we now would be climbing faster than all of the previous part of the flight!

Yes, that was the estimate that Bill gave me over the phone, but it was an -estimate- feel free to add +20% to 30% :)

The climb would have an exponential curve due to the trailing parachute, so it was not a typical linear ascent in our case.

We will be flying calibrated tests here shortly, we are still debugging the hardware, but have made huge progress.

Afternoon Michael.

Care to guess the curve?

Say from SL to 30K rate?
30 to 60 rate?
60 to 90 rate,
and 90+ rate.

Try your best guesstimate?

Joe

From: Mike Manes
Topic: 8221 Message: 8259

Michael makes an excellent point. This is perzactly how a super-pressure balloon operates - by holding a fixed volume and floating at an altitude where the mass of the displaced volume of air equals the mass of the balloon + gas + payload. Normally, the latex would not tolerate that much tension and would burst, but with such a light neck load and at that unusually high altitude, maybe it could?

It's also possible that a leak developed at the neck. The neck on a 3000 gm Totex is pretty stiff, and it's nearly impossible to fold it over to tie it off after a fill. That's why EOSS uses a modified PVC reducer and 1/2" NPT-M plug on 3000's.

Another possible causal mechanism is perforation by a meteor. I'll now avert my eyes and plug my ears to escape your jeers and evil laughter.

Thats what I'm crunching numbers on right now Mike, a low pressure
equivalent of a super pressure system.

With the giant volume of this balloon. It easily has the volume to be
able to generate quite a LOT of weight differential.

The question is if the latex has enough tensile strength to hold the
pressure in.

That part I'm working on.

Okay, I'll pipe in about the meteor. I'll break them into three groups based on mass.

First is the typical meteor we see at night. They are some 60 to 80 miles above the earth. Most are the size of a grain of sand or smaller and they won't survive their passage. They end up as some of the dust you sweep out of your house. The bit of dust that survives floats to the ground over a long period of time as a gentle rain of stony or metallic dust.

By the time larger meteors (less than 60 tons) reach the denser atmopshere, they have aerobraked enough to fall at terminal velocity. These make it to the ground for collectors and museums to purchase. Fresh meteorites are actually cold, not glowing hot. Ablation has melted their surface and as it streamed away, the vaporized melt took heat with it. Meteoriods have been cold soaking in the space for billions of years and a brief passage through the atmosphere doesn't heat up their interiors greatly (plus they made a passage through an extremely cold stratosphere to reach the ground). The largest intact meteorites in collections are 60 tons and they land with a thud, producing a minor pit in the ground. I don't think its likely that a tumbling stone will make a small hole in a balloon upon impact.

Meteors more than 60 tons will continue to fall at cosmic velocities because they are too massive for the atmosphere to slow down. If one of those impacted the balloon, there would be a substantial impact site on the ground below (or if large enough, we'd all be dead). These meteors are bright, even during the day and the impact site would be destroyed. Unless I've missed something in the news, that didn't happen.

So meteorite impact? I don't see how.

By the way, in space they're called meteoroids.
As the glowing streak across the sky, they're called meteors (the brightest are called bollides).
On the ground they're called meteorites.
If you think you have a meteorite but it turns out to be a plain 'ol earth rock, its called a meteorwrong.

I've added a simple plot of the dynamic viscosity of the standard atmosphere on the files page. It is interesting to note the increase in the dynamic viscosity above 30 km.
Since the Reynolds number is very small, the drag force on the balloon follows Stokes' Law.
 The increase in the dynamic viscosity will result in a decrease in the ascent velocity.
 This could be a contributing factor to the ascent profile of K6RPT-14 on Monday.

I have wanted to write yet another balloon lift calculator and this flight presented a question on why it slowed. I decided to see what the data looks like.

I have attached a spreadsheet that calculates the free lift every 500ft using the US Standard Atmosphere 1976 as the basis.

The one difference I did was add a pressure differential between the internal (helium pressure) and atmospheric pressure (Delta pressure inside balloon in PSI on spreadsheet) If you set this delta (blue cell) to 0 in the spreadsheet the lift is constant all the way up. If you set it to 0.01 psi it shows the lift dropping to 0 @ 120,000 feet. If this delta pressure is very low for most of the flight but increases significantly near burst this curve would be even more dramatic.

Let me know if you see anything wrong with this calculation.

Nice work, Jerry. Now if we can relate lift to an ascent rate (accounting for drag changes due to Reynolds number) and have it model the flight's ascent rate, then you're on your way to talking me into the pressurization theory. It'd help even more if we can show that the level-off point for a smaller balloon isn't reached over typical altitudes.

At first blush, a 0.01 in pressure differential is plausible to my mind.

Now all we need is a well-calibrated and high-resolution psid gauge in a future balloon. Hmm......

Hank and Mike,
Sometimes I confuse myself with what I write.
It looks like Jerry's spreadsheet addresses most of my concerns.
However, I am also wondering about the temperature of the gas inside the balloon envelope compared to the air temperature which is clearly warming. Is it possible that the temperature of the gas inside the latex balloon lags the external temperature? This would have a similar effect to Jerry's pressure difference.

Thanks Mark,
I guess nobody has found a bad assumption in my data yet.

As for calculating ascent rate, that is a little more difficult. The Cd (and underlying Reynolds number) is going to change as the balloon shape changes with altitude. I have been trying to find something that is reasonable but I'm not sure it is really possible though.

As for the pressure and the actual curve, there is information from Michael's presentation as well as references on the web that pressure will increase fairly significantly when you approach burst diameter. If you think that the pressure differential is fairly low until say 90% of burst diameter, the free lift would be flat and then quickly fall off just before burst.

I might have to buy some 100gm balloons and measure the delta pressure while I fill them with air to burst. Then correlate that with Michael's future flights to see if it scales.

Does anyone have any data on other flights that have turned to floaters? I would like to see if they fit the data.

I think a quote from one of my team members is appropriate for this: If it's worth engineering it's worth over engineering.

8272. Re: [GPSL] CNSP (K6RPT-14) flight ascent profile

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-02 01:29:41 UTC
From: Mike Manes
Topic: 8221 Message: 8272

There's the rub. If latex were that strong unconditionally, then all of our flights would be floaters rather than bursters. The hard part of developing a superpressure balloon is finding envelope material that's both light and strong. It can be done easily with ordinary film with 50 gm payloads and float altitudes in the troposphere.

From: Mark Caviezel
Topic: 8273 Message: 8273

Jerry,
I took a look at your spreadsheet.
Can you explain the 0.01 psid internal pressure? Seems high by more than an order of magnatude at launch, at least the way I analyze balloon pressures and stresses.

Topic: 8221 Message: 8274

Terminal velocity, given a fixed drag area, varies inversely with the square root of air density. So a meteoroid (thenkyew) will fall ten times as fast at 100K' (10 mbar) than it will at sea level. Now, kinetic energy varies as the square of velocity, yielding 100x the energy at 100K' vs the deck.

So an object in free fall thru the atmosphere will carry kinetic energy inversely proportional to air density.

Enough to puncture a latex envelope? Beats me, but not out of the question.

Ain't physics wunnerful?

It's really a SWAG but I'm not sure it is that far off. A 10 meter altitude change is about 0.01PSI. In normal breathing the pressure in your lungs is changes +- 0.06psi.

And in reality I don't expect the delta pressure to be that high until you are close to the burst point of the balloon. Until I can find some better numbers on what the curve looks like as you approach burst I didn't want to guess on the shape of that curve.

Hi Jerry,

Hey, neat work!

The only problem that I can see is the assumption of a constant gage pressure inside the balloon. Some folks have observed a marked rise in gage pressure as the envelope approaches its burst diameter. In fact, Space Data uses that parameter to initiate a gas dump in order to achieve a stable float. So if the gage pressure rises with envelope expansion, then one might expect to see a flatter free lift curve at lower altitudes.

And I noticed that you'd included a Coefficient of Drag (Cd) constant, perhaps in anticipation of cutting an ascent rate computation. When I did that, I never came close to the near-constant ascent rate that we're accustomed to seeing empirically. Turns out that Cd isn't constant due to some rather large variations in Reynold's Number. I think Nick Hanks discussed his findings in that regard at GPSL a few years ago.

Hi Jerry,

I don't think the test of the small balloons will scale very well for us.

The tensile strength is pretty close to the same balloon to balloon, Or
at least the tthree I tested, (300, 600, 1500 Gram sizes) all had
almost identical tensile strengths.

Taking that into account, pressure, and the radius, determine the
point of failure of the sphere,

The smaller the radius the higher the pressure it can hold back before
giving up.

But then again the larger sphere because of it's volume, does not need
to generate as much pressure, to lessen it's lifting capabilities.

8279. Re: [GPSL] New file uploaded to GPSL

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-02 02:38:35 UTC
From: Mike Manes
Topic: 1529 Message: 8279

I think Mike of ARBONET has figured out that the payload that reads
that pressure transducer must be attached right to the balloon neck,
thus obviating the normal balloon - lift line - parachute - payload
order. Either that, or link the transducer data at the balloon
down the string via a wireless link, e.g. Bluetooth. If the lift
line were in the form of a rope ladder to eliminate twisting, a
wired link could work - but what a mess to bring back on the 'chute
apex on descent!

Hi Howard,

As I mentioned in an earlier post, He seems to absorb solar radiation
and keep in inside the envelope. So if anything, I'd expect the He
bubble to be a bit warmer than the surrounding air. But He also
has an extraordinarily large specific heat, which is why it's used
as a heat transfer medium for nuclear reactors; so it could provide
the thermal storage mass that you propose.

That kinda suggests that any experiments that measure balloon gas
pressure might also consider throwing in a temperature measurement
as well.

A small logger right with the transducer might be the way to go. You'd need time hacks (easy enough) and could then time-sync the pressure values with GPS data on the main payload after recovery.

There are some Honeywell pressure sensors that could have the required resolution but the extreme cold may ruin the calibration and make the values untrustworthy.

8282. Re: [GPSL] New file uploaded to GPSL

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-02 13:16:05 UTC
From: L. Paul Verhage
Topic: 1529 Message: 8282

This was making me think we need a small BalloonSat inside the balloon. The Xbee radio at Parallax is only $19 and has the range. I can donate a BalloonSat Mini to the cause. I have Xbee radio boards for robotics that will attach to the Mini. What kind of flight computer is in the payload? My BalloonSat Extreme will record GPS data and listen to the BalloonSat Mini inside the balloon.

What pressure sensor is recommended?

This series has I2C digital output and either 3.3 or 5.0 V for supply
voltage:
http://sensing.honeywell.com/index.cfm/ci_id/155937/la_id/1/document/1/re_id/0

Since we are measuring very small pressure differentials, I would suggest
the smallest range available (the +/-5 in H2O version measures +/-0.18
psi). Mouser has at least some of these sensor types in stock. The
documentation is somewhat inconsistent, but with about 12-bit (4096 count)
resolution, the resolution is about .0001 psi. The trouble might be that
it's only good down to 0C calibrated and minimum operating temp is -20C. It
may be hard to get one that's fully rated down to the temps we need, but
maybe it's functional enough.

I think the cold is gonna possibly be a problem. But a flight could
always do it again like the Abornet gang did where the balloon was right
at the payload. and the sensor was inside nice and toasty.

8285. Re: [GPSL] New file uploaded to GPSL

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-02 14:17:09 UTC
From: L. Paul Verhage
Topic: 1529 Message: 8285
Attachments: 1 described; binary payloads are missing from this source WARC

I've downloaded the datasheet and will order a few sensors this weekend.

Cold could be a problem, but I don't know about running the sensor inside the near spacecraft. I'm thinking that running a hose to the payload could create issues. The sensor inside the balloon and a radio link would seem conceptually simpler (but also colder as Joe mentioned). Joe, what idea did you have in mind?

I would be interested in gettng the experiment back. I think we could tie the experiment to the load line so when the balloon bursts, it comes back with the 'chute. I can include a temperature and relative humidity sensor with the BalloonSat Mini (maybe a BalloonSat Easy since the sensor is I2C). The extra data ought to be useful. The BalloonSat flight computer digitizes to 10 bits of resolution. That's 0.5 deg C resolution and about 0.4% in RH.

Paul

What Pressure Range did you order?

> I'm thinking that running a hose to the payload could create issues.
That is the problem. And other than what the ABORNET gang did I at this
early morning moment, just don't see a safe alternative.
> The sensor inside the balloon and a radio link would seem conceptually

> have in mind?
Sadly none any better than the ARBORNET method. Does anyone know how
the University of Minnesota gang did theirs? I know they ran some
flights, but i never heard about the success of them or of any data that
came from them.
> I would be interested in gettng the experiment back.
He he he don't we all!
> I think we could tie the experiment to the load line so when the
> balloon bursts, it comes back with the 'chute.
I think the inverted system again as ABORNET did would be best. But
possibly with one change, instead of the main chute being under the
payload, have that be only a tiny drogue chute, that after PBC is all
over with and the payload is falling in the correct manner then it
deploys the main chute.

8287. K6RPT-14 balloon didn□t shred up like my 1500g flights.

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-02 14:38:04 UTC
From: k6rpt
Topic: 8287 Message: 8287

I just received an email with pictures of the balloon and payload from the property owner, looks like the balloon didn't shred up like my 1500g flights.

You Know? I Propose something that we all should do, especially once the new groups are all laid out and finalized. Like this whole discussion shouldn't be happening on the GPSL list.

But to re name the subject lines when ever the body does not any longer match the subject line. Like this thread of messages haven't had anything at all to do with a file that was up-loaded to he group site.

I changed tyhe Subject Line To Match what is IN the Body of THIS message. Or at least the Main thought of the message.

Having a clear and detailed true subject line would be very nice. Yes?

Interesting,

Granted I have yet to fly a 3000 Grammer, But the dozens of 1500's and
few 2000's that we have flown, we never ever get that much balloon back.

hmmmm? the Mystery Deepens!

The pinhole theory might fit into this too? That it got large enough at
the end to stretch open and slowly vent, (Caused the slowing of rise)
but then the continued stretching and it's defect gave a weak point for
a simple zipper tear to happen and one side of the balloon and it simply
un zipped and it really diddn't explode as usual. Also this may answer
why the max altitude was lower than expected because of the defect too.

I think the difference is the maker of the balloon. One has a hard neck on it (Kaymont?) the other doesn't. This one shreds to nothing in our experice but the other brand (Kaysam) without the hard neck does not.

Why I don't know but this is what we have observed.

I've had it happen both ways. The old Kaysams with the cardboard joiner
have ripped off clean right at that joint and I've had Kaymonts come back
with 80% still attached to the neck, vice versa too.

Anything from Kaysam has to be at least a decade old if not more
true? And they had that hard ring in the neck. I never ever knew what
the purpose of was.

Kaymont, is actually a Totex balloon Made in japan. kaynont is just
their Distributor.

Anything to do with Kaysam i ignore, I flew maybe dozen of their
balloons and was dissapointed on their performance on every flight. Yes
some were surplus, and a few were new too.

Kaysam had the ring and hard neck, Kaymont (Totex) does not.

We don't have much choice when it comes to balloons though, do we. A few months ago I looked into those balloons from China and they turned out to be pure latex (not neoprene or chloroprene which is a mix of latex and neoprene). They were very expensive, even in large batches.

8294. Pressure and temperature sensors inside balloon

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-02 15:50:36 UTC
From: BASE
Topic: 8294 Message: 8294

Minnesota and Taylor have both flown sensors inside the balloon. Taylor has done it many times.

The following link shows how James Flaten's students did it at Minnesota.

http://www.taylor.edu/dotAsset/177043.pdf

I know that Taylor partially inflates their balloons before inserting the sensor stick.

In June 2009 I attended a launch by Dr. Flaten. His students attached the sensor to a pole that was stuck inside the balloon. I thought for sure it would poke and burst the balloon, but nope, they knew exactly what they were doing. The pole kept the sensor somewhere near the center of the balloon's volume.

I just looked at that PDF, and it isn't what we need.

It is a simple pressure ambient pressure. What numbers we need are
differential pressure.

Not what the pressure is inside the balloon. But what the difference is
between inside and outside the balloon.

For the pressure measurements, I was thinking of a PVC pipe the same diameter as the ID of the balloon neck and putting all the sensors in that. Bottom would be capped with a hole open to atmosphere for ambient readings, top would be sealed except for short hose to measure internal pressure. Put batteries, sensor, radio or logger inside PVC pipe. Place an eyebolt in cap on bottom (nut/washer, then epoxy over?) to attach load line. Zip-tie neck onto pipe, but you'd need a ridge or groove on the pipe to prevent pipe from pulling out of neck (or a non-skid coating on outside of pipe).

The pdf flies describe how the sensors are mounted inside the balloon. Of course, to do a differential pressure you would use a different sensor with one port inside the balloon and the other port outside of the balloon.

To measure pressure inside the balloon, you can do it at least two ways:

1) A differential pressure sensor inside the balloon with one side capped off; this presents a known relative value (the captive part) as a constant of which you compare the variable pressure of interest inside the balloon. This is the way to go with the rod sensor mentioned by Howard, where we want to measure the change in pressure inside the balloon near the center. This will reflect the change in He pressure in a captive environment with the variable being the compression created by the latex.

2) A standard pressure sensor as shown in the ARBONET presentation at GPSL-2010 and flown in 2009. This measures the difference in pressure at the neck of the balloon against the ambient outside pressure plus the compression provided by the balloon.

Outside of impurities in the He and the point of measurement, the two should track relative to each other. The heavier impurities will show up in the neck of the balloon (standard air caught inside the envelope prior to inflation) and will show a lower reading overall than the unit sensing the air in the middle or top of the balloon.

I would like to see the results if we flew both. That would make for more gray-matter grinding discussions!

For sensors, I am using the Freescale 0.3 PSI amplified unit. Provides an analog output that is already corrected over a standard temperature range, and runs +/- for those areas we may see actual vacuum in the neck.

What model is your pressure sensor and where did you get it?

Sounds like we should fly two BalloonSats inside the balloon and interesting observation about "heavier" air settling into the neck of the balloon.

From: Jerry Gable
Topic: 8294 Message: 8305

If we are primarily interested in the differential pressure as the balloon approaches burst, does it make sense to test a few on the ground with just an air inflation? Might be interesting to do a setup with a high speed camera to watch the burst.

Jerry

All the discussion on pressure at burst, I never thought to check the manufacturer's data. I went to the Kaymont website and they do list a burst pressure.

For the 3000 gram balloon it is 3.7 hectopascals 0.054 PSI.
For the 1500 gram balloon it is 6.3hPa or 0.091 PSI

So it looks like my 0.01 SWAG was actually quite low. Now it would be good to verify that number and come up with a starting point and shape of the curve.

Smaller balloon, larger pressure. Perhaps this is due to its tighter curvature directing more force towards the center of the balloon. Same reason that it's more difficult to begin blowing up a balloon than it is to continue blowing it up.

Does that also tell us that a smaller balloon is more likely to go neutrally bouyant?

Paul

No,

People keep doing that.

The numbers on the site is not the differential pressure. it is the
atmospheric pressure that the balloon will be at when it bursts.

It's just another way to state the bursting altitude.

Which of course is also meaningless because burst altitude all depends
on the amount of gas mainly placed in the balloon.

Well it was a fun idea at least. The numbers do line up with their listed burst altitude.

Back to the drawing board.

No,

People keep doing that.

The numbers on the site is not the differential pressure. it is the atmospheric pressure that the balloon will be at when it bursts.

It's just another way to state the bursting altitude.

Which of course is also meaningless because burst altitude all depends on the amount of gas mainly placed in the balloon.

8310. K6RPT-14 Balloon Could Not Have Pressurized

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-02 21:35:57 UTC
From: Joe
Topic: 8310 Message: 8310
Attachments: 1 described; binary payloads are missing from this source WARC

I have been crunching some numbers, I was going to see if this flight began to pressurize, and what pressure it may have gotten to when it gave up, but after crunching this first set of numbers I honestly do not think this balloon got even close to start to pressurize when it ended it's flight.

Anyone care to double check my math below?

==========
Balloon Type and weight, Totex TA-3000 *3000* gram weight
Nozzle Lift *1080* Grams

Total system lift, balloon and nozzle Lift
(the amount of lift needed to be provided by the lifting gas) *4080* grams.

At Sea level 1 cubic meter of HE weighs *178.6* Grams.
At Sea Level 1 Cubic Meter of "Air" weighs *1225* Grams.

So, 1 cubic meter of HE is *1046.4* Grams lighter than 1 cubic meter of "Air"

So taking the needed amount of lift as seen above (*4080* grams)
Divided by the amount of lift that 1 cubic meter of HE provides, will give you the amount of HE needed for the flight.

4080 / 1046.4 = *3.899* cubic meters.

To confirm the numbers,,

3.899 cubic meters of "Air" weighs *4776* Grams and
3.899 cubic meters of HE weighs *695* Grams.

"Air" weight minus HE weight =

4776 - 695 = 4081 Grams (Close enough for needed system flight)
==========
TA-3000 Balloon Volume at Burst *1150* cubic meters.

Assuming the data from above is correct, I calculate that my estimated burst should have been at *129500* feet.

==========

Now looking at that flight rate of climb chart that someone made, it is very obvious that something very drastic happened at right about *115 thousand* feet.

Was the balloon almost full? And It has started to pressurize?

Nope not a chance.

The Initial *3.899* cubic meters at sea level of HE, has expanded at *115,000* feet to only *582* cubic meters!

It is just barely past being half full. So I think there is no way this could have started to pressurize.

Now what happened? Is anyone's guess.

I'm leaning towards a minor defect, that started to vent gas, and as it lasted longer and longer it got bigger and bigger, till it zippered up the whole side of the balloon, which also gives good evidence of the large amount or remaining balloon. Where instead of literally exploding like we all have seen, it more just split up one side like spandex on some 500 pound woman at Wal*Mart

8311. SSOK Jan 2000 floater

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-02 21:54:30 UTC
From: Mark Conner
Topic: 8311 Message: 8311

http://showcase.netins.net/web/wallio/SSOK.html

I'm pretty sure this was a 3000g balloon, but the payload was probably 1 lb or a bit more. I can't recall if this used hydrogen or helium. Anyway, it too slowed its ascent rate way down and achieved near floating conditions, but Pete's lasted 2.5 hours instead of bursting almost immediately after ascent stopped. Pete's flight was using a pre-WAAS GPS, so altitudes would be less accurate.

Bill, didn't one of your earlier floaters (one of them without the intentional hole in the plug) do roughly the same thing before sunset?

I'm still thinking feature (physical cause) rather than frequent bug (partial failure of some sort). Now to figure out what it is.....

Then again we had our floater that floated all day and into the
evening, where we launched at sun up. from here in southwest Wisconsin,
it went all day, and flew into indiana, then came back to fly over Elgin
,IL. and pop at sundown. And land in the NW suburbs of Chicago.

This was way in the pre any GPS days, all was triangulation, for
location, and who was hearing it from how far away to determine altitude.

And all data was relayed via the 40 meter tracking net.

what a blast!

Topic: 8310 Message: 8313

So if you set the delta pressure to 0 on my spreadsheet it will show very close to the same numbers that you have.

I take it you don't believe the inside vs outside pressure is real or affects the lift to the extent needed to explain this balloon. In reality we will probably never know on this balloon and one hypothesis is as good as the next. I guess i will have to see if I can find any more evidence for my hypothesis :-)

One thing I noticed was the ascent rate on the chart. It looks like the first 40K feet was done in 45 minutes, 80K in 90 minutes. 889 fpm seems like a lot faster than the expected.

Does that seem within the range expected from the free lift given?

Also, what kind of burst altitude (or volume) tolerance is seen on these balloons?

I haven't used them but have you looked at the APRS trackers from Byonics or Big Red Bee? I am thinking about getting one as a backup tracker so I am interested how they worked out for other's.

Unless of course you are talking about the ground radio then never mind :)

You can occasionally find a Kenwood D7 on eBay or elsewhere which is a handheld radio with a built-in TNC to decode the packets from a balloons xmitter. You'll also need a GPS either connected directly or with which to use by hand entering the coordinates. Entering by hand is cumbersome but does work.

I really like the Argent Data <http://www.argentdata.com/catalog/> stuff. The OT2M with interface with a Garmin Nuvi 350 (that model only for the way you want it to work). In my balloons I have connected an Open Tracker + to an old handi-talkie and a GPS for reporting the balloon's position. On the ground I use both a Kenwood D7 as well as my Alinco DR-135 with an Argent Data T2-135<https://www.argentdata.com/catalog/product_info.php?cPath=22&products_id=55&osCsid=87a246f0261e9c593d5ea2a43a88382c>and
a Garmin Nuvi. The T2-135 is essentially an OT2M on a small board
that
interfaces with the digital side of the Alinco 2 meter radio. What's great for balloon recovery is that the Nuvi 350 plots the balloons position onscreen (but doesn't decode and display its altitude - the Kenwood D7 does, however) and you can use the Garmin navigation capabilities to find it.

I also have an Argent Data OT2M that just yesterday I configured for a fill-in digipeater here at home. I bring that up only because I really believe in the Argent stuff and first learned of it here by asking a similar question to yours. You will be happy with their products.

All that said keep in mind there is a pretty steep learning curve to APRS tracking and HABing. It's a helluva lot of fun but there is a lot to learn. HABing is seemingly simple - and it is in concept - but pulling off a flight is not as easy as it seems.

Oh, the Alinco DR-135 can be found new online for about $170 and the T2-135 board is an additional $75. Gamin Nuvi 350s are harder to find but out there if you look. Price has gone up in the last year or so as so many APRS guys are buying them up (or so I'm guessing). Oh, yeah - you'll also need a cable from Argent to connect the radio to the Nuvi. I don't recall which one it is now but it's on the web site.

Yup and the lift is flatline across the flight as it should be.

I quite don't understand the massive curve when there is a delta
pressure, of the pressure is a constant 0.01 psi through the flight,
shouldn't the amount of compressed gas that is heavier be constant
through the flight? Why does the amount of density change with altitude
if the pressure differential is the same for all altitudes?

Try your sheet with a more typical payload flight say a 1500 gram
balloon, and 6 pounds of lift at the nozzle, what does the machine spit
out then?

I have been crunching some numbers on guessing psi at burst, but i need
to measure a few more parameters some, but for the 3000 gram balloon I
have a wide swing of estimated PSI at burst, anyplace between 0.019 and
0.075 psi at burst. still working on this tho..
>
> I take it you don't believe the inside vs outside pressure is real or
> affects the lift to the extent needed to explain this balloon.
Not that I don't believe it. I'm just comparing what pressures were
measured in other flights, Like the chart from ARBORNET when the
balloon was 1/2 full, is at the point of the flight where it most likely
had the LEAST amount of differential pressure at the time.

Not to me, with 1 pound (a typical amount we use for a windy day
launch. we average 90% of the time in that range of speed high 800's
and low 900's with 8 oz of extra lift we get in the 600's on the average.

>
> Does that seem within the range expected from the free lift given?
If anything to me it seems a little slow with 1.6 extra, 1.6 extra I
would expect close to 1000 or even 1100 ft/min.
>
> Also, what kind of burst altitude (or volume) tolerance is seen on
> these balloons?
We have yet to have one burst early, 90% usually are withinn + or - 1000
feet of our prediction, if it ever is way off it's always been on the
high side. like NSS-50 we estimated it should pop pretty low because we
used a small balloon and way over inflated it, we thought a 85K pop but
it made it to a litle over 93K

But most of the times our alt predictions are pretty close.

That's true. Of course, you'd give up a cutdown, unless you were willing
to lose the logger.

I think that getting a very accurate static port for the transducer would
be very important, in light of the small differential pressures you'd
be measuring. Might be tough to get in the wake of the ascending balloon.
And I'm clueless re how to know when you had the static port just right.

DigiKey carries a line of very sensitive diff pressure sensors:

http://search.digikey.com/scripts/DkSearch/dksus.dll

Some are good down to -40C - but pricey? Yeah!

DigiKey also carries 'em:

http://search.digikey.com/scripts/DkSearch/dksus.dll?Detail&name=480-2522-5-ND

But only good down to -20C and still pricey! One could keep it above 0C with
a thermostatic heater and some thermal insulation - just make the sensing
tubes long enough to keep the coolth out. Analog Devices makes a nice
resistance-programmable electronic thermostat IC - used it on my first
Li-ion flight test.

It's axiomatic that two parallel lines on a flight string will twist
themselves together to form a single, uniform rope. Even if one is
a signal cable. Better to live with the shards coming back with the
'chute.

From: Mike Manes
Topic: 8287 Message: 8323

I've brought back as much as 6 lb or 90% of a 3000 gm Totex shards.
No telling how they'll burst.

8324. Re: [GPSL] Subject Line & Body Of Message Matching,,,

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-03 04:26:47 UTC
From: Mike Manes
Topic: 1529 Message: 8324

Interesting threads do tend to wander away from the original message,
but changing the subject line does break that thread, and that's
crude, rude and socially unacceptable to some - not me - but my
beloved bride was recently pilloried unmercifully for committing that
offense on her mythology reflector.

I don't give a hoot.

There's no telling. Some balloons break and leave nothing but the neck
tied to the lift line, while others of the same loading and altitude,
even on the same day, bring back dang near all of the envelope mass.

Since putting the fast release on all of our 'chutes, it's not a issue
for us any more (unless the release ices up :=( ).

You'd need one monster garbage bag to match the 35-foot burst diameter
of a 1200 gm latex! And then you'd have to figure out how to terminate
it.

I see that they measured the absolute pressure inside the balloon, which one would expect to be just slightly greater than the ambient air pressure. How much greater really can't be determined to any degree of accuracy from this experiment, even if the ambient pressure were measured separately, due to the "small differences in large numbers" effect.

Now I know this experiment was intended to test the ideal gas law, so those methods were valid, except for the rather coarse determination of the balloon volume from its image.

I think what we need is an accurate measurement of the differential pressure that's forcing the latex envelope to expand. And y'know? That could be done on the deck with a tethered balloon and a simple water manometer. Not as much fun as flying, tho. And it wouldn't create any head-scratching about what the Bernoulli effects of the airflow over the envelope might have as well.

I bought the last batch of Kaysam 3000 gram balloons before they closed their factory....I think that was in 2004...I still have a few of those left that I haven't flown....they performed well...I've flown about half the balloons I got in that last batch.

You'd need one monster garbage bag to match the 35-foot burst diameter
of a 1200 gm latex! And then you'd have to figure out how to terminate
it.

My Battery has passed away in my high accuracy Micrometer. 0.000001 accuracy.

can anyone here do a measurement for me? Take a piece of balloon, (part from a left over flight of course, I wouldn't ask you to do this on a new balloon) and measure it's thickness at total rest. where it's not stretched at all.

and then have someone stretch it to it's it cant stretch any further. the point where it's just about to break, and measure it's thickness at that point too.

anyone? Please?

8332. Static balloon internal pressure test

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-03 16:29:24 UTC
From: Jerry Gable
Topic: 8294 Message: 8332

So I have decided I am going to do a static test on the ground. I don't have a 3000g balloon to try this on but I do have a 600 gram I will sacrifice for the cause. I think I will get a couple 100g or so balloons so I can gauge how size affects the pressure.

I have order a .3PSI differential pressure gauge from DigiKey and will probably set up a water gauge also. I plan on using air and if I can get a building large enough I will hang it from the ceiling for the test.

Now for a couple of questions.
1. Does anyone see why this won't be a valid measurement of the delta pressure (on the ground with air)?

2. Anyone have any balloons they want to donate to the experiment? I am in Phoenix if that matters.

It will probably be a couple of weeks before I can get everything set up.

From: Jerry Gable
Topic: 8294 Message: 8334

Joe,
The transducer puts out 1V per kPA so the voltage should be around .1V for the 600G balloon if you guesses are correct. That will only be .277" of water so it won't be readable on a water column.

I'll try it on the small balloon and if you are close I will have to go for the much more expensive transducer.

So what is your guess on the curve? I am assuming that you think it will be very close to 0 (less that 0.001psi) for most of the time and increase to your predicted amount at burst. My guess is it will start climbing around 90% of the diameter,

Jerry,

Joe mentioned temperature and I'll do the same - it's not only the temp at burst but the exposure to the cold on the way up. You also have UV exposure which might modify the latex properties. Neither of these will be possible to simulate well on the ground.

I would inflate the balloon at a rate roughly matching what the balloon experiences in a real flight. I assume you'll stop the inflation periodically to measure the pressure differential? Measuring while inflating may not be valid, depending on how everything is hooked up.

I have some 100g balloons I could donate (somewhat old, unfortunately).

How I came to those numbers is where I used to work, was at a plastic factory where we made many specialty plastics. and one of their test equipment was a tensile strength test equipment.

you would cut with this Die a special sized piece of the material to be tested. And you place it in the machine, and it stretches the test sample till it breaks, and you get the tensile strength.

We ran about a dozen tests, and they all were pretty consistent.

I then took that number and used it in the formula to calculate for a given diameter of a sphere at what PSI will exceed the tensile strength of the surface of the sphere.

And those numbers are what came out.

Now on this,, You ask....

So what is your guess on the curve? I am assuming that you think it will be very close to 0 (less that 0.001psi) for most of the time and increase to your predicted amount at burst. My guess is it will start climbing around 90% of the diameter,

That is hard to say. I'd be willing to say the curve is accurate, But it is a very low pressure curve, Sooo, low, that it has little to no effect on the HE density and buoyancy factor. I'd like to see what the numbers are, at that beginning of fill.

Say my guesses are right? If we take the ARBORNET pressure graph. and say it was a 1500 gram balloon,, (I don't remember what it was)

And burst was at the 197 minute point, and on that chart it had a value of about 28 on the left side. So say a 28 equals 0.0065 PSI

If this is true and that scale is linear, that those peaks shortly after launch would have peaked out at what about, 0.0104 PSI?

After those small peaks, it all dropps from there.

agree? Anyone? Anyone?

Bueller?

Joe,

I don't have the curve from ARBORNE, is it posted somewhere?

Also while you are predicting, what would you expect as a delta for say a 10" party balloon? Probably not even the same material but I may see if I can do a simple experiment this weekend.

From: Jerry Gable
Topic: 8294 Message: 8338

I finally found some balloon pressures here:
http://scipp.ucsc.edu/outreach/balloon/labs/InflationExp.htm

They don't say what size it is but the comment that 5' diameter is no where near burst leads me to believe it is in the 100-200 gram range.

Anyway, from their numbers, it looks like the pressure starts at 0.07psi and settles down to 0.03 during the middle inflation period. I would guess that burst would be above the initial pressure.

But we still have too many unknowns.

8340. Re: [GPSL] Static balloon internal pressure test

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-03 20:07:46 UTC
From: Joe
Topic: 8294 Message: 8340
Attachments: 1 described; binary payloads are missing from this source WARC

yeah without knowing what size the balloon was. the numbers really
can't tell us a lot.

but the highest pressure apparently both with that group and the
ARBORNET flight is not at burst, but just past the barely inflated
diameter phase.

8341. Re: [GPSL] K6RPT-14 Balloon Could Not Have Pressurized

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-04 01:21:06 UTC
From: Mike Manes
Topic: 8310 Message: 8341

Nice piece of analysis, Joe. Turns out that K6RPT-14 was expected to
make 129K', just as your figures show. So the early stall and low
burst at 123K' was not expected and is indicative of an anomaly; just
what it was is the topic of this quiz.

I'm stickin' with the meteroid, Paul!

From: Mike Manes
Topic: 8294 Message: 8342

The only reason that the pressure will vary between the top and bottom
of the balloon would be due to gravity gradient. Period. Makes no
difference if the gas species separate inside the envelope. And
the gravity gradient in the Earth's atmosphere over a 50 foot difference
in elevation is vanishingly small.

Consider that pressure is simply due to the recoil of gas molecules
striking the interior surface of the envelope - or the diaphragm of
a interior pressure transducer. This is basic principle behind the
ideal gas law: PV = nRT or P = nRT/V. For constant nRT, P varies
inversely with volume, V, and vice versa.

8343. Re: [GPSL] Pressure and temperature sensors inside balloon

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-04 02:36:06 UTC
From: Mike Manes
Topic: 8294 Message: 8343

Hi Jerry,

Yeah! That works around the question of getting an accurate ambient
pressure reading at a static port, since the balloon is stationary,
and if one uses a water manometer to measure the interior pressure,
the cost of a sensitive transducer and logger or telemetry scheme,
along with compensation for low-temperature errors, is
eliminated.

One could use natural gas (methane, MW = 16) for the fill in order to
get the balloon erect, thus saving the cost of compressed gas.

Not nearly as much fun as a real flight, however. Unless one is careless
about fire safety!

In addition,

While HE won't combine with other gasses to form other compounds,, if
there happen to be other gasses in the envelope, would the HE stratify,
(stay at the top) if it's lighter, or will it just mix in with the
other gasses and become a mix of both evenly belended throughout the
envelope.

Plus How would this happen anyway? If the gas inthe balloon isn't 100%
HE or H2, it's gota be awful close. to whatever purity the gas in the
bottle was.

3.7 hectopascals equals 1.5 inches of water, and also the barometric pressure
at 126K'. So a 3000 gm latex would have an internal pressure 2x that of
the 126K' baro pressure. That means the balloon volume would be only
half that of an unconstrained bolus of He at that altitude, and the
density of balloon gas would thus be twice what we would assume,
perhaps enough to kill off the excess lift needed to sustain an ascent.

This could explain the loss of lift that we saw.

I think the 3.7 hPa came from my misreading of the Kaymont tables. But what he is saying is if the pressure in the balloon is higher than the external pressure the balloon will have less lift.

I think his point is if the internal pressure is slightly higher inside the balloon then there will be a loss of lift from the He. My calculations are that tha pressure needs to be about 0.01 to show the loss in lift from the balloon that started this.

That is about 10x what you believe it to be. Again I think we need some actual measurements to prove or disprove this cause.

But there is always the meteor theory.

8348. Re: [GPSL] K6RPT-14 Balloon Could Not Have Pressurized

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-04 03:43:12 UTC
From: Mike Manes
Topic: 8310 Message: 8348

Joe,

Consider a case where the differential pressure equals the standard
atmospheric pressure at some altitude. In that case, the gas pressure
would be twice the baro pressure, and the balloon volume half what it
would be with zero differential pressure. Since the balloon is displacing
half the air, then its gross lift would also be cut in half.

Topic: 8294 Message: 8350

Hi Jerry,

You could use a simple water manometer (U-shaped clear plastic tube) half full of water plus a ruler to measure the pressure. Cheaper and quite sensitive down to a fraction of an inch of water column.

Another technique is to immerse the hose carrying the balloon pressure into a beaker of water, and measure the depth at which bubbles just start to appear at the end of the hose.

1 kPa = 4.01" WC, so 0.1 kPa = 0.401" WC. Either is easily readable
using a common ruler.

From: Mike Manes
Topic: 8294 Message: 8352

Hmmm - the chart of pressure in that link show pressures between .097 and 0.98 Atm, or over 10 psi. I don't think one can blow that much pressure by mouth, so I suspect the pressure scale is either wrong or it's absolute pressure vice the differential that we're interested in.

The He will rise to the top in the presence of other gasses in the envelope. This is what happens with a ZP balloon. As the envelope rises, the He bubble stays on top, and as it expands, it pushes the air in bottom out the vent. This continues until all the air is expelled and He fills the entire envelope.

But you're right about a He-filled latex. Ain't much air in there - just what might have snuck in when the balloon was rolled out prior to filling.

I got those numbers from Wolfram-Alpha: http://www.wolframalpha.com/
Try it. You'll like it!

All I'm trying to point out is that the internal pressure in a latex
balloon will compress the fill gas and thus reduce its lift compared
to a zero-pressure condition. At the altitudes we fly, that effect
is minimal, but getting way up above 120K', it can cause lift to decay,
perhaps to the point that there's no free lift left.

This >won't< happen with a ZP balloon, and that's probably why ZPs are
used for the really tall flights.

My Guess for the 600 balloon with the water column method would work
out to

0.0065 pound/square inch = 0.179 919 381 48 Water Column [inch]

Now I'm not sure. that with a water column that has an area of 1 square
inch right? IE: a tube with a ID of 0.5625 will equal a 1 square inch
surface area.

Now If I remember right, the surface area is what counts where the
pressure presses on the water?

so if the opening to the water at the balloon neck is 0.5625 is has
the 1 square inch area. BUT......

if you make the tubing smaller after that,, then you can act as a
multiplier, If i remember correctly. Like if the tubing is 1/2 square
inch in area, then the water column will be twice as accurate motion
wise. 1/4 square inch area, 4 times the accuracy IE 1 square inch of
pressure would move the water up 4 inches.

If i remember this correctly.

Your Mileage May Vary..

From: Mike Manes
Topic: 8294 Message: 8357

Tubing diameter is irrelevant. The larger area of a larger tube does
yield more net force on the column, but that's perfectly balanced by
the larger weight of the displaced column.

Wiki "manometer".

This is the way HVAC tech check gas pressure.

A water manometer can be made more sensitive by slanting it, so a
given vertical displacement yields a larger lateral displacement.
This is used in some pitot tube type anemometers.

ABSOLUTELY!, that's how super Pressure balloons work.
>
> I think his point is if the internal pressure is slightly higher
> inside the balloon then there will be a loss of lift from the He.
Yup, IF there is any higher pressure, it will lift less because it is
denser than it would be if the pressures were equal.
> My calculations are that tha pressure needs to be about 0.01 to show
> the loss in lift from the balloon that started this.
0.01 PSI? differential.

Ok, I calculate that the balloon at burst was only 73% filled. so how
much pressure there was, is questionable. But it was a volume of 847
cubic meters. which means it is displacing 847 cubic meters of "Air"
which weighs 4828 grams.

ambient air pressure is,
0.057772 PSI, Sooooo, say the balloon now stays at this pressure, it
can not expand anymore, the outside pressure has to drop to, 0.047772
PSI to give you the 0.01 PSI differential right? and at that pressure
differential a cubic meter of "Air" weighs 0.0046 Kg,

soooo, that density of the volume displaced weighs, 3300 grams. thats
now the balloon has gained weight by 1528 grams. far more than enough
to cancel out the little over 700 grams of lift you had true.

But myself I don't think the balloon would be able to build up 0.01 PSI.
of pressure.

This stuff is a blast! he he he

Thinking More here,

I know a scary think me thinking.

The pressure chart of the ARBORNET guys. Looks like we can or should be if we get a good enough sensor to monitor the pressure to note when the pressure suddenly starts to rise before burst. It could be I suspect even be automated, that after it reaches a below a certain low point, zero or near zero according to that graph. once it hits that point it resets the system then whenever the pressure rises above say when ever the pressure at 5 or higher it opens a valve to let this pressure out. Once it gets below 5 it closes. it could be automatic. and of course make a equivalent of a zero pressure PE balloon.

I also thought the idea of venting gas to have the payload come down under the control of the balloon. Like we did on a two balloon flight we did.

But if that pressure curve is correct, we probably won't be able to do that. because once we loose the pressure of before burst we are down to zero pressure, and it shouldn't vent anymore.

hmmmmm?

8360. Joe's numbers on latex balloon internal pressure

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-04 15:37:26 UTC
From: Mark Caviezel
Topic: 8360 Message: 8360

I used a free body analysis technique, control plane through the equator of the balloon, and came up with internal pressure numbers of around 0.01 psi at Earth Surface. This shows correlation with Joe's numbers.

0.1 psi is MUCH more than we'll see in a latex balloon.

Comment: it's hard to beat a water manometer for making the measurements that Jerry wants to do. I will suggest use of a 10:1 slope in the leg that you're reading, will allow you much greater granularity than using a vertical leg. Back when we were still learning about how to build zero pressure balloons, we conducted a bunch of calibrated manometer inflations of ZP's to verify that the material and seam strength as built was the same as the multiple coupon samples that we tested to yield and failure. I use a variac'ed leaf blower to produce a variable pressure air source.

Comment: let's not forget that the pressure is not uniform throughout the balloon (for a balloon filled with buoyant gas): It is highest on top. Remember the 3rd grade science demonstration of a water filled bucket with holes in the side? The hole on bottom has the highest hydrostatic pressure, and the lateral stream of water shoots our further than the hole half way down the side of the bucket. Flip that bucket upside down and fill it with rising helium rather than falling water and you'll get the same effect.

best

- Mark

Thanks for the insightful comments, Mark, as always. I've been watching this thread and just biting my tongue at times. I almost added a little story about pressure testing my cylindrical superpressure design to failure by sealing a big chunk of dry ice inside, but decided to save that for another time....

Mike's comments and yours about the water manometre were especially helpful... It's amazing how even those of us who are accustomed to finding the most off-the-wall solutions (e.g., my ex describes - with great disdain - my early solar Montgolfiere experiments as "flying trash bags into the sky") can overlook such a fundamental instrument. Enough of these damned transducers already - it's back to making glassware over a Bunsen for me! :)

I have the VX-8R and depended on it (along with the internet) at GPSL 2010 to track and find our ROBOMO1 balloon

I got it off ebay last year for ~$355+shipping for just the radio.

It is a great radio after you devote the time to learning to use, but I'd suggest getting the software, mic cable, and gps, from guys I seen with that stuff, those solves hours/days of frustration getting it setup into the nice tracking, packeting, quad-band it can be.

Subject: [GPSL] Hand Held APRS

I am looking to purchase a hand held radio capable of APRS for my son Brenden KJ6HVP. I was looking at the Yaesu VX-8 which HRO is selling for $430 plus GPS module, I am hoping for something a little less expensive. I have heard of them going for less on eBay. I was wondering what others on this list are using to track their payloads.

Thanks,
Tim KJ6HSX

Agreed! Almost by a factor of Ten. BUT,, I may be a little light on the pressure capabilities by the nature of our tester that tested the tensile strength of the balloon material. I'm thinking it may be in the real world a little higher, Because of when die cutting the test samples any microscopic nicks and dings in the cutting edge must add a possible defect to the edge of the test sample I would think, and cause the sample to break slightly prematurely at these defect points. I would think.. the Die looks perfect, but what really is ya know?

*This I also will agree with. and it may answer why just before the balloon nears burst diameters on the ARBORNET graphs that the pressure says zero or even vacuum. The amount of stress from the LARGE latex isn't strong enough yet to over come the stratification effects.

But I would think once the balloon starts to pressureize, the the internal pressures would even out.

Now here is where that long tube with several differential sensors to measure various heights in the balloon would be very interesting.

8364. Re: [GPSL] Joe's numbers on latex balloon internal pressure

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-04 21:42:48 UTC
From: Jerry Gable
Topic: 8360 Message: 8364

So from the conversation here is what I think the consensus is.

0.01psi is probably typical for the internal pressure on a large balloon.
On the ground with air the pressure will be pretty consistent throughout the balloon.
With helium there will be a pressure gradient with the highest pressure at the top of the balloon.
This may explain the 0 pressure ARBORNET saw during part of the flight if their sensor was near the bottom of the balloon.
And this is why zero pressure balloons don't loose all of their helium.
A Manometer is going to be the most accurate way to measure this pressure
Slant the tube to increase the movement of water and ease of reading.

I have also found a graph that claims the pressure as the balloon inflates will initially be high and almost immediately drop to about 1/2 this initial value.
The pressure will then rise slowly but linearly until it is significantly higher than the initial high pressure at burst.

What is your favorite formula for predicting ascent rate? I have found several formulas and the answers vary by 2 to 3 X from each other.

And last, are you guys getting tired of the speculation? Should some of us take this offline and maybe only post results here?
Personally I would like to here all of your opinions on this.

Jerry

But I would think once the balloon starts to pressureize, the the
internal pressures would even out.

Now here is where that long tube with several differential sensors to
measure various heights in the balloon would be very interesting.

Here is my Fill and measurement device. The copper tube up the middle is the measurement port. The rubber ball on the end is to help prevent adding a "rapid deflation port" to the balloon. The grid is 1/2" in case you are trying to figure out the scale. Comments are always welcome.

Where did you find that one?

It seems different from the arbornet one, Where it does start high but then slowly drops through what 75% of the flight to then run at almost zero for a while to only rise quickly at the end.

>
> What is your favorite formula for predicting ascent rate? I have
> found several formulas and the answers vary by 2 to 3 X from each other.
Same here, our flights never match the "Predicted" rates. We NEVER EVER come close to the lift suggested and used by others.

Our regardless of payload and or balloon always go by total free lift Balloon, payload and all. And after 20+ years this is what we do, and what we have had. I can not explain why the numbers do not match the "Formulas" But be it a simple tracker only that weighs 3/4 pound, or a pair of payloads and we are at the legal limit of 12 pounds, we always fly the same free lift.

And the amount is only determined by two things. and that is still only two. and they are weighed against eachother

One is landing location, do we need the flight to go faster to shorten the landing zone, or slower to cross over a different zone. But the amounts we fly are as follows.

Winds conditions. Dead Calm to 10 Mph surface winds 8 ounces of positive lift.

10 to 20 MPh 1 pound.

Over 20 MPh 2 Pounds.
Thats it!

And that is all we have ever done.

And the rate of climb has also been pretty consistent too

8 oz lift 600 to 700 maybe 750 max.

1 pound lift 700 to 900

2 pounds 900 to 1100

This is regardless if the payload weighs 10 oz or 10 pounds! an TA 300
balloon or a TA 2000 balloon.
>

That's perzactly how Space Data controls its balloon-borne cell sites.
See:
http://www.spacedata.net/documents/SkySite_Telemetry_Overview_Jan06.pdf
That's more of a sales brochure, but it does give you an idea of how
their system works. Their CEO gave a technical presentation a the
SWRI LCANS Conference a couple of years ago.

Hi Robert,

Save yourself some trouble and make your manometer out of clear Tygon
tubing. And for static fill for pressure tests, I think one could
just use the hose from the Bunsen burner to fill with methane (CH4)
rather than wasting that non-renewable resource, He.

Hi Mark,

I don't think the water-in-bucket experiment works with light gasses,
where molecules are not bound into a fluid, but are free to fly about
randomly. Consider, if one were to take both experiments into a
zero-gravity environment, you wouldn't see the same results as on a
terrestrial surface. Given that, then any pressure gradient along
a vertical axis in the balloon would be due to gravitational effects.
See my earlier post.

But I'm open to seeing contrary experimental results.

Well, that works if one has someplace tall and wide enough to support
a full balloon from the neck (35 ft diameter for a 1200).

Or use a lighter-than-air gas and do it outside in the clear. Since yer
not going for altitude, methane (natural gas) will do just fine. The
service pressure in my home after the meter is 6.5" WC (measured with a
manomoter, BTW). 1000 cuft costs a bit over a buck. Obvious fire
protection caveats apply, of course.

Wotever rings yer chimes ...

8377. GPS & 60k Feet

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-05 16:11:59 UTC
From: HarryM
Topic: 8377 Message: 8377

I would like to submit the following info for the "GPS above 60,000 feet" data.

Pharos USA (Microsoft) GPS
Model GPS-360
P/N:X10-72407 / 360-1000-02

Chipset:

SIRF
GPS2E LP7451
0248 DFBFBA
KC358AE

Startup Strings:

$PharNav S/W Version: 07S203
$Build date: Sep 23 2003 10:53:18
$SiRF FAM Version 231.000.000ES
$TOW: 347454
$WK: 1598
$POS: -533500 -5127694 3743167
$CLK: 95329
$CHNL:12

$Baud rate: 4800 System clock: 12.277MHz
$HW Type: S2AM
$Asic Version: 0x23
$Clock Source: GPSCLK
$Internal Beacon: None

INFO:

This GPS has a USB interface, but does provide NMEA TTL serial output at the GPS. It will run on 3-5vdc. It always starts up in Thailand, but does aquire a 3D lock very rapidly. It is a good small $20 GPS for APRS below 75,000 feet with appropriate drivers from Pharos. It will not work above 75,00 feet as documented in corespondence from the manufacturer (see below).

Pinouts: http://www.flickr.com/photos/imager/4383334403/

.....

Hello,

The max altitude for the iGPS-360 receiver is 75K. Unfortunately, we will not be able to release the command strings for the receiver or be able to modify the i-GPS-360 receiver to work above 60,000 feet. Thank You.

Best regards,

Technical Support

8378. hydrostatic pressure and 'heliostatic' pressure.

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-05 19:26:42 UTC
From: Mark Caviezel
Topic: 8378 Message: 8378

(from Mike) I don't think the water-in-bucket experiment works with light gasses,

where molecules are not bound into a fluid,

Comment: both water in a bucket and helium in a balloon are indeed fluids. The holey water bucket experiment produces increasing pressure (hydrostatic pressure) with increasing depth because of the high density of the water and gravity. The example I site, the holey balloon generates increasing 'heliostatic pressure' with height above the mouth of the balloon because of the difference in density of the balloon gas versus the surrounding fluid, air and gravity effecting both fluids. You could even do the holey bucket experiment with a heavier than air gas, such as CO2. Water has a high density so the hydrostatic gradient is huge compared to the surrounding air pressure gradient. For the water bucket example, it is standard practice to ignore the effects of the ambient fluid, air. This example is in pretty much every basic physics text book. For the balloon example, the density of the inflation gas will normally be much closer to the ambient fluid, air, so the buoyancy effects should be taken into account.

And of course if we go in to a zero-gravity situation there is no buoyancy whatsoever, so there is no hydrostatic or heliostatic pressure.

best

- Mark

8379. Re: [GPSL] Joe's numbers on latex balloon internal pressure

Yahoo group: GPSL (2009 — 2010)

From: Jerry Gable
Topic: 8360 Message: 8379

OK, I have a long weekend so I decided to try out the test. I don't have the 100 gram balloons yet so I bought a 72 inch party balloon. It weighed in at 160 grams. It popped at around 9 feet long so I am going to say it is close to the 100 gram Kaymont with heavier latex.

I built the Manometer and tried for the 10x design but ended up with a 5x model instead.

As you will see in the pictures I trashed most of the house setting this up. I'll be in the doghouse for a few days:)

So for the results:

* The initial pressure went to 0.14 PSI but then quickly dropped back to about 0.1 PSI.

* The pressure then slowly dropped to 0.83 PSI. This looks about 1/2 way through the time but I started off with a lot lower flow. I would guess the low point would have occurred around 1/4 of the final time if the flow had been constant.

* The pressure then increased pretty linearly to 0.103 just before burst.Conclusions:

* The pressure in this balloon was probably quite a bit higher than a Kaymont balloon. Joe estimated a burst pressure of 0.0311 on the Kaymont 100. I predict it will be closer to 0.06 on that balloon.
* I would think that a balloon at launch is at or beyond the low point in the curve.
* The pressure will increase throughout the flight. This would be the average pressure in the balloon (higher at the top, lower at the bottom).
For the next test:

* I need a bigger building.
* I need to be able to measure the size (the plan this time didn't work out) and ideally the flow rate.

Here are pictures and the results
The fill and measure device:
http://dl.dropbox.com/u/9446302/BalloonBurstTest1/MeasureAndFill.jpg
The balloon at close to full size and Manometer:
http://dl.dropbox.com/u/9446302/BalloonBurstTest1/BurstTest1Setup.JPG
The results:
http://dl.dropbox.com/u/9446302/BalloonBurstTest1/Test1Results.xlsx

All comments welcome

I agree on the thought of the thicker latex.

I wonder how consistent these balloons are if you were to run the test
again if you would get similar results.

THEN a real interesting test would be to run it again this time with the
fill apparatus at the bottom and fill with HE to see what the pressure
does, Have the sensor as close to the neck as possible.. etc...this
would show if there is stratification in a latex balloon or not.

Or since it looks movable hey place the sensor opening at the neck
and push it up as far as possible and see if it changes at all.

Me myself for some reason find it hard to believe.

From: Jerry Gable
Topic: 8360 Message: 8381

Joe,

I doubt they are very consistent. I bought 5 - 100 gram balloons on ebay for the next test. They will be more consistent. I have a 600 gram I also plan on poping. I have a 1000 gram that I might pop if I find the correct space.

From what I remember, helium and air will not stratify in the balloon, they will be completely mixed.

As Mark C. has pointed out there will be a hydrostatic pressure difference in the balloon. Think of it this way, at the top you have a column of helium pushing up. At the bottom you have a shorter column pushing up. So in the opposite direction of the atmosphere the helium pressure will be greatest at the top. This is why a zero pressure balloon (or hot air balloon for that matter) can be open at the bottom.

I do believe that the average pressure in the balloon has to equal what my measurement is when filling with air.

I also believe I would see the same results if the balloon resting on the ground. There is just a lot more chance that something will puncture the balloon. I may try hanging and resting on the ground with the 100 gram balloons. I may also try one with helium.

Jerry

Hi Mark,

By your argument, if a He-filled balloon were in an H2 atmosphere, the internal pressure gradient would reverse, with more pressure on the bottom than the top.

How does the gas inside the balloon "know" what the density of the gas outside the balloon is?

He and air >will< separate, much the same way that oil will float to
the top in water. This happens in ZP balloons. As the He bubble expands
during ascent, it pushes any air (and there is plenty in there once the
envelope plumps out) out the vents at the bottom.

The argument that a significant pressure gradient appears in a latex
balloon remains specious in my mind because it presumes the gas inside
the balloon knows what the density of the gas outside is.

Jerry,
Thanks for sharing your results. I have access to a wonderful space to do static fill tests:
http://www.depauw.edu/photos/Publications_Repository/2010/4/26/04Julian_Panorama-c1.JPG
The atrium can easily handle balloons up to 28 feet across, and with a little extra effort, I think we can fill balloons up to 34 feet across.
I have some older Kaysam 350 gram (3) and one 1000 gram balloon, plus new Kaymont/Totex 600 and 1200 gram balloons (although I'll probably fly most of these).
I'm not sure when we will have the time to do the static tests, since we have a busy flight schedule this fall, but it will be fun.
Thanks for the inspiration,Howard

OK, I have a long weekend so I decided to try out the test. I don't have the 100 gram balloons yet so I bought a 72 inch party balloon. It weighed in at 160 grams. It popped at around 9 feet long so I am going to say it is close to the 100 gram Kaymont with heavier latex.

I built the Manometer and tried for the 10x design but ended up with a 5x model instead.

As you will see in the pictures I trashed most of the house setting this up. I'll be in the doghouse for a few days:)

So for the results:
The initial pressure went to 0.14 PSI but then quickly dropped back to about 0.1 PSI. The pressure then slowly dropped to 0.83 PSI. This looks about 1/2 way through the time but I started off with a lot lower flow. I would guess
the low point would have occurred around 1/4 of the final time if the flow had been constant. The pressure then increased pretty linearly to 0.103 just before burst.Conclusions:
The pressure in this balloon was probably quite a bit higher than a Kaymont balloon. Joe estimated a burst pressure of 0.0311 on the Kaymont 100. I predict it will be closer to 0.06 on that balloon.I would think that a balloon at launch is at or beyond the low point in the curve.The pressure will increase throughout the flight. This would be the average pressure in the balloon (higher at the top, lower at the bottom).
For the next test:
I need a bigger building.I need to be able to measure the size (the plan this time didn't work out) and ideally the flow rate.

Here are pictures and
the results

The fill and measure device:
http://dl.dropbox.com/u/9446302/BalloonBurstTest1/MeasureAndFill.jpg
The balloon at close to full size and Manometer:

(from Mike)
By your argument, if a He-filled balloon were in an H2 atmosphere, the internal pressure gradient would reverse, with more pressure on the bottom than the top.
ANSWER>>>>>> Yes.

(from Mike)
How does the gas inside the balloon "know" what the density of the gas outside the balloon is?
ANSWER>>>>>> In direct terms, it does not know the density, but the PRESSURE is transmitted through the flexible wall of the balloon, be it latex or plastic.

Howard,
It looks like a great place to do it but how do you think they would feel about the talc in the balloons spread all over everything? I have seen some balloons that have quite a bit of powder in them.

Mark,
Do you have any idea what the gradient in a balloon would be? I would think it would be pretty small in a 20 ft balloon.

Jerry:
Looks like a great set up! Thanks for sharing it.
It appears that you have at most a couple inches of vertical travel for your (water?) column. Unless I am screwing up the math, this would seem to give a maximum pressure reading capability of about 0.07 psi, far less than your reported pressure max values. Or maybe you are using some super-dense liquid in your manometer?

Comment: The shape of the balloon is no where close to a sphere. Ascent rate calculations normally assume the balloon is spherical, which is not a great assumption. I've not yet seen exhaustive wind tunnel data for real latex balloon shapes at the Reynolds numbers of interest. After a couple years of trying to be rather scientific about calculating exact fill quantities, free lift, resulting ascent rate, I adopted the practice of planning for 1-3 pounds of free lift for a <12 lb latex mission. The guys who really care are the altitude record seekers. And they now have a difficult task to break the current record.

Mark,
Please check my math on the Manometer. Here is what I have.

The measurement portion of the tube is 30 inches long with a vertical change of 3 inches. So if the water moves the full 30 inches that is 3 inches of vertical travel and the high pressure side goes down 3 inches for a 6 inch vertical delta. 6 X 0.036126 = 0.217 PSI full scale

So I ended up with a 5X Manometer

Does that make sense?
Jerry

I have trouble with that also. For normal flights, it's not a problem if you use the blue Energizer lithium batteries. Having the camera screen on keeps the camera warmer which also has benefits.

In the past, I've shut the screen off using the camera controls after scripting it seemed hit-and-miss. Perhaps others have had better luck.

Brenden,

I don't recall ever having a failure of the screen off command, but I wrote the script for an A570is powershot. Here is the page where I documented the process:

http://eoss.org/hardware/canon_a570is.htm

I don't have the camera anymore, it's in the EOSS "warehouse". So I can't do any testing but, as you can see from the video linked to the above page, the display does turn off.

It was my experience that the camera would take over 1400 pictures on a single set of lithiums when placed in a freezer (-5F or so). So, I think it should fly through one mission with the display on. Course... it all depends on the frequency of your shooting schedule. I take photos once every 6 or so seconds for a while during launch and climb out. Then the camera backs off to a slower rate until it once again approaches the ground. We run something like 750 pictures per flight.

I finally got my 570IS to run MY script at startup. There's an item in the menu that's fairly obvious once you see it. I think the problem that I had was that I changed the value, but didn't actually SET it before exiting the menu. Once I held my nose right, it took.

Sorry, I don't have the camera nearby to tell you what that setting was.

So, your pressure gradient wouldn't appear in a rigid envelope, e.g., a fully inflated ZP or SP envelope? Or are you arguing that the tensile stress in the envelope skin will vary from top to bottom as a function of the ambient gas density? Kind of a stretch, isn't it?

Correct. The manometer is read as the vertical difference in height
between the menisci on the two sides of the tube.

8397. manometer math

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-07 12:47:05 UTC
From: Mark Caviezel
Topic: 8397 Message: 8397

Mark,
Please check my math on the Manometer. Here is what I have.

The measurement portion of the tube is 30 inches long with a vertical change of 3 inches. So if the water moves the full 30 inches that is 3 inches of vertical travel and the high pressure side goes down 3 inches for a 6 inch vertical delta. 6 X 0.036126 = 0.217 PSI full scale

So I ended up with a 5X Manometer

Does that make sense?
>>>>>>>>>>>>>>> yes, looks good. Ok now I am curious if that balloon you used for test is significantly stretchier than the latex balloons that most ARHAB guys fly.

8398. internal gas pressure

Yahoo group: GPSL (2009 — 2010)

(from Mike) So, your pressure gradient wouldn't appear in a rigid envelope, e.g., a fully inflated ZP or SP envelope? Or are you arguing that the tensile stress in the envelope skin will vary from top to bottom as a function of the ambient gas density? Kind of a stretch, isn't it?

>>>>>> Answer>>>> Just as the hydrostatic head is a function of depth in a metal bucket or a similar depth plastic bad filled with water, the gas static head of a ZP helium balloon is function of the height from the bottom of the helium to the top of the balloon. The tensile stress in the envelope skin is

stress = (internal pressure) x (radius of curvature) / (2 * skin thickness)

The NASA ULDB guys try to reduce the skin stress by using external tendons to decrease the radius of curvature. Most hot air balloons also have a certain amount of bulbousness for the same reason.

The whole CHDK is a prety neat system, but man....

I'm trying to get my A550 to run the script I select, but often I'm finding it's a different script or the silly default one. Consistency is my biggest problem now. After that, I want to default the script to mine.

What I'd like to see is a CHDK editor that will syntax check your script befre loadig it in the camera. I find the parse errors my camera reports unhelpful, as they don't tell me where the problem lies.

Otherwise, cool over all.

I agree with Mike on what he says here.

And I still think that once pressure starts to build I can not see how
the density can be any different. Like I said otherwise every balloon
would only pop at the top?

Ok i'll go for that, to the point of when there is any pressure inside.
Once pressure starts to build I'm thinking it will pretty quickly even
out throughout the envelope. If this is not true, then in theroy every
balloon should pop at the top of the balloon where the greatest stress
will be.
>
> I do believe that the average pressure in the balloon has to equal

> gram balloons. I may also try one with helium.
When you do with the helium,

I'd only go with enough HE to get it reliably off the ground, having it
be 100% HE would I bet put un due stress with it trying to lift like who
knows how many pounds? Whats the burst diameter? How much would it be
trying to lift at burst?

Id get a good reliable amount of lift, then , fill the remainder with air.

Hey even better yet......

Can you again hang it up side down and fill it only with air? But not
only keep track with pressure, but it's weight?

Whenever pressure is falling the balloon should weigh less and pressure
rising it should weigh more.

Talking about a difference in pressure in the balloon....

The balloon rises due to bouyancy. Is this due to the greater hydrostatic pressure at the top of the balloon? That greater pressure on top creates the force (pressure X area) that makes the balloon accelerate up (until balanced by drag pushing down).

Topic: 8397 Message: 8403

Mark,
I'm not sure how to interpret the term stretchier. Doing just a kind of feel test on a piece of this balloon vs a chunk from 1000 g balloon that I have I would say that it takes a little more effort to stretch my test balloon. The latex also feels a little thicker so that is to be expected.

I have some 100g balloons showing up this week. I plan on repeating the test with a couple of them as a baseline.

Then all I need is to find a building to pop a 600g balloon in to get an idea of how all of this scales for larger balloons.

Subject: [GPSL] manometer math

Mark,
Please check my math on the Manometer. Here is what I have.

The measurement portion of the tube is 30 inches long with a vertical change of 3 inches. So if the water moves the full 30 inches that is 3 inches of vertical travel and the high pressure side goes down 3 inches for a 6 inch vertical delta. 6 X 0.036126 = 0.217 PSI full scale

So I ended up with a 5X Manometer

Does that make sense?
>>>>>>>>>>>>>>> yes, looks good. Ok now I am curious if that balloon you used for test is
>>>>>>>>>>>>>>>significantly stretchier than the latex balloons that most ARHAB guys fly.

Our 560 the screen off wouldn't work also,

But the camera has flown on several flights with screen on and had
plenty of power left on landing, even when recording Video.

SigCHDK Guru's,

I messed around with CHDK and an intervalometer script on my SX200is last night for the first time. I can't believe all the functionality it provides. I had some fun with it.

I want to d/l some more scripts. Can you provide me with some links? I don't plan on writing my own at this time. Just use some pre-made ones & mod them.

I want to try a motion detection script for lightning stills and to control video.

I've been lurking on this thread for some time, and finally decided to chime in with my $.02.

1. The static ground tests sound really good, but I'm not clear on how you will simultaneously add gas to the balloon, and measure the results in a highly-accurate and meaningful way. To inflate the balloon, you will have a hose entering the neck, with a higher-pressure source connected at the other end. Even if it's *slightly* higher in pressure, it seems unlikely that you will be able to detect such a low pressure differential seconds before burst, especially with the gas continuing to flow into the balloon.

2. I personally wouldn't think air vs. helium would make any difference in this test. If you do plan on wasting helium, just remember that filling a 600 gram balloon with a K tank to ~6 diameter is a WHOLE different story than filling that balloon to ~25' in diameter.

3. As far as the pressure gradient is concerned, I remember very clearly my physics teacher stating that the pressure inside of closed vessel is equal and opposite in all directions. That being said, it's possible that his description was an over-simplification for a Physics 101 course.

I feel with the setup he has shown and if his flow is slow enough like a
flight where it's gonna take 2 hours to get to burst, the flow will be
slow enough that it shouldn't make any difference.

I agree, either hang it and fill from the top, or add just enough HE
to make it airborne and a little more, then fill the rest with air.

Zack,

Glad to here you are watching this.

As far as measuring the pressure and filling the balloon, this is what I am using: http://dl.dropbox.com/u/9446302/MeasureAndFill.jpg

It is made of 3/4" PVC. The air enters the balloon through the valve and fitting at the top of the picture. The port on the bottom of the picture is plugged. There is a 1/4 copper tube that goes through the middle of the PVC and extends about 18 inches inside of the balloon. This is used to measure the pressure. I drilled a hole through a small plastic ball and glued it on the end to prevent it from poking a hole in the balloon during insertion. The end of the tube is open.

During my experiment this last weekend I could not detect any pressure change when the air flow was turned on or off. Not even a mm of change in the manometer level so I think the fill and measurement are pretty isolated from each other.

I don't really plan on buying helium for a static test. I am trying to do this indoors and I don't think releasing that much helium would be safe.

8410. Re: [GPSL] gas-static pressure, air column, water column, helium column

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-07 23:02:10 UTC
From: Jerry Gable
Topic: 8385 Message: 8410

On the pressure gradient topic, I have no idea what is correct but one thing I have observed is when ANSR launches a balloon, they have a solid piece of PVC that they leave in the neck for the flight. I have watched them hold the neck, unscrew the fitting in this PVC and add a plug. It appears that no helium is venting during this time. That implies that the pressure at the top is > than at the bottom.

It may just be that the pressure on the balloon is balanced because of the lift pulling against the weight on the neck.

Once I am done with my static pressure tests I may fill a 100g balloon with He and see if I can measure a gradient or see what happens if I have the neck open and constrain the balloon from the top (throw a net over it). If someone has some ideas on some experiments I am open to suggestions.

The Key word again is it appears. But when you have hundreds of cubic
feet in a balloon, and even if 10 cubic feet were to escape would you
see the difference? and then how many cubic feet under like 0.01 PSI is
actually going to escape?

The 100 gram won't be a fair test. the internal pressure even when
barely filled will be many many times the pressure on a 1000 or 3000
gram balloon.

There is pressure there. You can refer to the flight graph presented at the GPSL this year by ARBONET. The pressure of the very lightly loaded 1200Gr balloon we flew was greatest on the ground and a few thousand feet in the air and then tailed off with altitude until just prior to burst. These were actual, in-flight pressure measurements with helium. Unless extremely lightly filled, such as a ZP balloon, there will be pressure at the neck.

Not an over simplification at all. Other than the slight effect of gravity, I believe this to be 100% correct, regardless of shape.

From: Mike Manes
Topic: 8398 Message: 8413

The hydrostatic pressure gradient in your holey water bucket is developed as that necessary to support the mass of the column of water above it. By the same token, the gradient in a gas balloon is developed as that necessary to support the mass of the column of gas above it; for He, that wouldn't amount to anything measurable with a water manometer. That is what I meant earlier by my reference to gravitational gradient.

And your explanation relating envelope skin stress as a function of pressure and curvature sheds no contrary light.

In both cases, we are referring to >absolute< pressures, independent of the ambient density outside the envelope. And in both cases, that pressure will >increase< towards the bottom of the envelope.

It's understandable to pass on the notion that the pressure of the lifting gas is greater at the top of the balloon, since that's where the force of the lifting gas is acting, isn't it? However, that force on the top of the balloon isn't due to the buoyancy of the gas, but rather due to the neck load and the mass of the envelope pulling down on the balloon and, during ascent, the drag of the air pounding down on the top of the balloon.

Imagine a balloon made from that rarest of all materials, Noweightum (created by expulsion of all Higg's Bosons from the envelope material), with no neck load, and with no drag load due to a strong updraft, i.e. zero vertical airspeed. Would there be any gradient that couldn't be accounted for by the simple hydrostatic model?

I view this lifting notion extremely simplified as pinching a slippery water-melon seed between your fingers, the pressure on the sides and bottom forces the seed to escape towards the area of less pressure, and in this case it is the slightly less pressure above the balloon due to the tiny relative displacement caused by the balloon and helium itself. Pretty amazing that this minuscule displacement in a virtual column of air can provide that much lift!

I found Noweightium impossible to find, so I started using LessaMassium, which is made by politely asking the helium atoms to share their electron bonds with one another only, rather than dispersing among the pesky nitrogen, oxygen and other over-weight neighbors, while also attracting free-agent helium atoms into the helium community during the ascent. Unfortunately, we can not share the details of the helium community contract we have with others, but in short, this arrangement promises 366,000 feet on our next flight unless atomic anti-segregation rules are enforced. We are still working on the details on how to tie our payloads the helium atoms, we are still seeking little tiny strings to accomplish the job.

NSTAR has some footage of a balloon slipping off the filler and flying
away. Mark, was the balloon flying away like a toy balloon filled with air,
or was it floating away?

8417. Re: [GPSL] gas-static pressure, air column, water column, helium column

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-08 13:43:40 UTC
From: Pete Lilja
Topic: 8385 Message: 8417

We recently had an escapee and while I stood mouth agape watching the 1200 gram He balloon float away I remember thinking it looked rather serene. The balloon was nearly filled to release size and when it spit the plug in it's nozzle and left it just sort of blobbed around and floated up. With no neck load it was just a free-form floating bag. It didn't spin like a released party balloon but it wasn't fill-stretched all that much either.

We use a PVC nozzle with a threaded plug when flying HABs. I, too, have noticed that when we pull the fill nozzle to place the screw-in plug for flight there is very little, if any, back pressure pushing out of the balloon. We always feel a sense of rush to get the balloon plugged but I really don't think it's necessary. It seems the lifting gas 'likes' to be in the balloon envelope!

From: Brenden Geary
Topic: 7187 Message: 8418

Thank you for all your guys' help. After hours of Google searches I finally understood CHDK enough to modify one of the scrips I found to work for us. I also found a way to shut off the display completely, all you have to do is plug in an AV out cable in and cut of the end.

The whole CHDK is a prety neat system, but man....

I'm trying to get my A550 to run the script I select, but often I'm finding it's a different script or the silly default one. Consistency is my biggest problem now. After that, I want to default the script to mine.

What I'd like to see is a CHDK editor that will syntax check your script befre loadig it in the camera. I find the parse errors my camera reports unhelpful, as they don't tell me where the problem lies.

Otherwise, cool over all.

Paul

On Mon, Sep 6, 2010 at 8:47 PM, Zack Clobes <zclobes@...> wrote:

I finally got my 570IS to run MY script at startup. There's an item in the menu that's fairly obvious once you see it. I think the problem that I had was that I changed the value, but didn't actually SET it before exiting the menu. Once I held my nose right, it took.

Sorry, I don't have the camera nearby to tell you what that setting was.

I'm trying to get a script to start up when I power up the camera. The Canon A550 wants to run its default script. Does anyone run their default script at power up?

Paul

On Mon, Sep 6, 2010 at 3:41 PM, Rick von Glahn <rick@fastmail.us> wrote:

Brenden,

I don't recall ever having a failure of the screen off command, but I wrote the script for an A570is powershot. Here is the page where I documented the

process:

http://eoss.org/hardware/canon_a570is.htm

I don't have the camera anymore, it's in the EOSS "warehouse". So I can't do

any testing but, as you can see from the video linked to the above page, the display does turn off.

It was my experience that the camera would take over 1400 pictures on a single set of lithiums when placed in a freezer (-5F or so). So, I think it

should fly through one mission with the display on. Course... it all depends on the frequency of your shooting schedule. I take photos once every 6 or so seconds for a while during launch and climb out. Then the camera backs off

to a slower rate until it once again approaches the ground. We run something like 750 pictures per flight.

8419. October Launch

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-08 19:28:14 UTC
From: L. Paul Verhage
Topic: 8419 Message: 8419

I've been asked about launching a balloon for Washburn Univeristy in Topeka in October. I'm wondering if I can shake up some help with filling, chasing, and recovery.

By the way, I just ordered a Find Me Spot. I'd like to send it up on this flight as a backup tracker (that only puts me 2 years behind Bill). I'd really like to put it into a back pack with a parachute for a Tickle Me Elmo doll and call the whole thing, Find Me Elmo.

Thanks,
Paul

Better yet, you can either launch from here, or drop Elmo here:

http://maps.google.com/maps?f=q&source=s_q&hl=en&geocode=&q=Elmo,+KS&sll=38.685543,-97.225657&sspn=0.029814,0.066047&ie=UTF8&hq=&hnear=Elmo,+Dickinson,+Kansas&ll=38.681791,-97.227416&spn=0.029816,0.066047&z=15

(we drove through here for GPSL 2002 recoveries)

8423. Re: [GPSL] gas-static pressure, air column, water column, helium column

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-09 04:51:18 UTC
From: Mike Manes
Topic: 8385 Message: 8423

The pressure inside a latex balloon on the deck that's filled for
flight that will expect the gas volume to expand some 100x is very
low - like a small fraction of an inch WC. And that's not going to
produce a sensible rush of gas out that 1/2" NPT orifice - but if one
dared to snort in a lungful of the gas just outside that orifice, one
could determine that, yes, Squeeky, it's He. Try it with a pibal
sometime.

Here's another experiment to determine the pressure difference
between the top and bottom of a balloon:

Rig up a pressure tap on the top of a balloon and feed it to
one side of a manometer, with the other side going to the neck
on the bottom. If there's a measurable pressure difference, then
disconnect the manometer and connect the two sensing lines together,
end to end. Since there's a pressure difference between the far
ends of the new 2-piece line, then there will be gas flow from the
high pressure end to the low pressure end, right? Put in a little
turbine, hook it to a generator and use it to power your payloads -
forever!

Or not.

Gasses don't behave like solids, and not all that much like liquids, either. Gas molecules are anti-social and will move to put as much space as possible between themselves and their neighbors, even risking bodily injury by banging against the walls of whatever encloses them.

I'm still waiting for CERN to respond to my order for a 3000 gm latex balloon that's had its Higgs bosons removed. Can't understand the delay. I mean, how much time in the LHC would it take? :=)

I saw a physics demonstration on SF6 several years ago. I was told there is
a danger in that you may not be able to clear the gas as fast from your
lungs. I suppose if you get light-headed, you need to stand on your head to
get it out of your lungs.

The balloon dropped almost like a rock, in this demo.

Cool stuff and a great insulator.

Yes it is, in recent years we have replaced all of our oil-filled circuit
breakers with SF6 circuit breakers in our substations.

Interesting. I figured it would be more difficult to seal a circuit breaker
air tight than it would be oil tight.

At K-State (that "other" Kansas school), they use it as an insulator for the
Van deGraff that powers their linear accelerator.

From: HarryM
Topic: 7187 Message: 8430

Paul,

On my camera it will display the line number of the
script error in the upper left of the screen.

For a debugger I d/l UBDebug and only briefly looked at it.
It may be what your looking for. You can find it here...
http://www.zenoshrdlu.com/kapstuff/zubdb.html

73 Harry KC5TRB

What I'd like to see is a CHDK editor that will syntax check your script befre loadig it in the camera. I find the parse errors my camera reports unhelpful, as they don't tell me where the problem lies.

Subject: [KNSP] NSTAR Flight 10-C postponed

Due to the probability of strong winds at the surface and aloft, NSTAR Flight 10-C will not take place this Sunday. Surface winds are expected to be at least 10 mph and gusts to 25 mph are possible. If we launched, the landing would be 20-25 miles south of Creston IA (a 125-mile drive from the launch site), which is farther than we really want to go.

Our next opportunity is either October 10 or 24.

CNSP is planning flight K6RPT-16, that will be a high altitude attempt.

APRS Tracking system is being put together with an estimated payload weight of 5 oz.

3000g Balloon, HE, Total Payload .31 lbs, Nozzle Lift 1.37 lbs, Free Lift 1.06 lbs, Time to Burst 3.7 hrs, Ascent Speed 610 to 665 fpm, Estimated Peak Altitude 137K

The target launch date is October 2010.

Morning Ron,

Will be watching with excitement again. I hope you the best, and we all hope something like last flight doesn't happen again.

Be sure to hit the E-Mail lists again BIG just before the launch a day or two so we know exactly when it's going.

Do you care to tell how you are calculating your burst altitude? Just curious.

8434. CHDK - Formatting Large SD Cards

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-11 15:24:39 UTC
From: HarryM
Topic: 8434 Message: 8434

I apologize for the wrong posting. I'm not sure what is happening.
The post is not what I sent... "Re: [KNSP] NSTAR Flight 10-C postponed".

Formatting large BOOT SD cards for CHDK

Does anyone have a proceedure to format larger than 4gb SD cards to boot for use with CHDK? I have tried every instruction on the Web that I could find and none will work. I have used CardTricks, HDhacker & HXD with no results. The camera I'm using is an SX-200is. I can get cards up to 4gb to boot just fine.

Might be the Camera,

We use a 16 gig card in our A560 and it works just fine.

Hi Joe,

We are just using Liftwin and I'm sure we will not get too that altitude.

We feel with the sharp decrease in the ascend rate, the last flight must have had a pinhole.

The last flight had an average ascend rate of 800 fpm so we dropped our free lift to 1 lb and reduced the weight of the APRS tracker to 5 oz (maybe under 5 oz, still testing), the fill will be reduced by 15 cubic feet.

We are open to any comments or suggestions.

Basically, you can't directly format cards larger than 4 Gb and have them work for CHDK. I believe it needs to be a FAT16 filesystem and 4 Gb is as big as you can go.

Others have gotten around this by putting two partitions on the card - a small FAT16 one for the CHDK stuff and FAT32 for the pictures. Try a Google search on "FAT16 FAT32 CHDK" to see if you can get a detailed how-to.

I was going to do that, then decided I'd just live with 4 Gb of pix per flight.

Now this IS interesting, hmmmm?

Now when is this formatting to happen? Is the Camera doing to
formatting? Or on your computer with a SD Card Reader?

I know I can with the SD Card reader format the 16 Gig card with no
problems at all.

But the next question is, does the camera do another formatting? I
don't remember seeing this happen if it did.

CANON HACK DEVELOPEMENT KIT
Partition/Format Larger than 4Gb SD Cards with 2 partions.

EUREKA! I HAVE FOUND IT!!!

After spending 12 frustrating hours yesterday I found the answer this am.
I found Web info on creating a dual partion card, but nothing I tried worked.
Here's what I found today that works and is pretty easy!

- Low level format card in camera. Card is now *Gb FAT32.
- Put card in card reader on the PC.
- Goto the SDM (StereoDataMaker) site... http://stereo.jpn.org/eng/sdm/index.htm
- Goto the "Downloads" and get "Common_files.zip"
- In the "Common_files.zip" you will find "sdminste.exe".
- Run "sdminste.exe". This is a pretty simple partioner & formatter.
- Make the 2mb partion BOOTABLE using "sdminste.exe"
- Unpack "SMALL" build of CHDK for your camera to the 2 MB partition using PC.
- Write protect card, camera now boots on card. "Swap partition".
- Unprotect card, card back in PC. Unpack "FULL" CHDK build to FAT32 partition.
- Card back in camera, "Firmware update" start method, "Swap partition".
- Remove card and Lock it. It should boot!

Note - Instead of using "Swap partition" in-camera I used "sdminste.exe"

This worked for me on an 8gb card!

From: Jerry Gable
Topic: 8432 Message: 8442

I haven't done all of the experiments yet but I will throw out my prediction based on a 0.01psi higher pressure in the balloon.

Burst altitude: 135K feet (without delta burst would be around 132K feet).
0 lift: 130K feet
50% lift: 110K feet

So my prediction says that the ascent will be significantly slowing around 110K feet and float around 130K feet.

It's an SX200-is.

I just did another 8Gb card and it took me 10 min to get
2 partions, formatted, bootable and CHDK loaded and working.

What Model is your camera?

Topic: 8434 Message: 8449

If you mean the SX200, Yes it will do the following...

1280 X 720 HD (30fps) 8Gb - 43 min
640 X 480 SD (30fps) 8Gb - 1 hr 35 min
320 X 240 LD (30fps) 8Gb - 4 hr 50 min

Max clip length = 30 min.
This might be extended in CHDK, but I haven't look at it yet.

Does it do Video?

Just did a 16Gb card and everything works well.

The SD card has a 2Mb FAT16 partition and a 15.7Gb FAT32 partition .
The 2Mb one is used only for boot.
CHDK and all data goes on the FAT32 partition.

The problem is the FAT 32 file system. The max file size is 4GB. Below copied from here: http://neuron2.net/LVG/filesize.html

In order to store files on a hard drive, your computer uses a file system. Depending on your operating system, there are many different file systems that you may be using. Here is a table that lists the maximum file sizes for different operating systems and file systems:
  Windows 95
(pre-OSR2) Windows 95 OSR2+,
Windows 98/SE/ME Windows NT 4.0 Windows 2000/XP
FAT16 2 GB 2 GB 4 GB 4 GB
FAT32 N/A 4 GB N/A 4 GB
NTFS N/A N/A Nearly unlimited Nearly unlimited

So, OK,

the max a file can be is 4 Gig,

How about what holds the files the SD card itself.?

I don't understand what you are asking. If they follow the fat32 spec it is limited to 4GB. They could create their own file system on the card but then you could only read it on that device.

Ron,

The -15 SSID is what a KNode reports for a noded non-SSID call (SSID = 0).
Why not use -11, APRS convention for a balloon?

The card can have more than 4GB total but one file cannot be larger than 4GB. So on your 16GB card you could have 4 - 4GB files. Or you could have a lot of smaller files that add up to 16GB total.

I have a cheap video camera that I fly that closes the current file and opens a new one every 30 minutes. After a flight I end up with 4 or 5 1.3GB files on an 8GB card.

Thank You! thats exactly what I would Like to do with our Canons with CHDK. But havent been able to get a scrip to work yet.

I have scripts that work great when taking pictures.

But need it to like

"Press Shutter Button"

wait 20 min,

"Press Shutter button"

wait 1 Minute

"Press shutter button"

wait 20 min

"Press Shutter button"

and on and on and on till the card is full.

then this awesome camera can be our camera for our ATV video flights.

Joe, here's a simple script that does what you want.
Change the sleep values to something in the second range
instead of minutes for initial testing. The values are
in 1000ths of a sec, so 1000 = 1 sec.

It loops until the batteries die!

73 Harry KC5TRB

```
rem KC5TRB script - take a pic after 20 min, wait 1 min, take another pic, etc.

@title TRB 20-1

:top

sleep 1200000 rem Wait for 20 min

press "shoot_half" rem Press shutter button halfway to get focus
sleep 3000 rem Wait 3 sec
press "shoot_full" rem Press shutter button all the way to take pic
release "shoot_full" rem Unpress the shutter button

sleep 60000 rem Wait for 1 min

press "shoot_half" rem Press shutter button halfway to get focus
sleep 3000 rem Wait 3 sec
press "shoot_full" rem Press shutter button all the way to take pic
release "shoot_full" rem Unpress the shutter button

goto "top" rem Do it again from TOP
```

Pete....best to call him on the phone and keep trying....last time I called he was out of 1500 gram balloons until October...but that may have changed.

- Bill

Also the 600 gram balloons that are currently on eBay for $20 each are excellent quality and appear to be only a year old. I'll do a seperate posting on this to the list.

Subject: [GPSL] Balloon Availability?

Has anyone been in recent contact with Paul F. at Kaymont? I've emailed several times in the last month or so inquiring about purchasing some balloons but have heard nothing back.

Thanks,

Pete

8468. eBay balloons for $20

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-12 06:05:52 UTC
From: wb8elk@aol.com
Topic: 8468 Message: 8468

I bought a bunch of these at $20 each....they are Kaymont 600 gram balloons from Navy surplus and seem to be pretty new stock....maybe only a year or two old....they are packaged in plastic wrap and then individually boxed.

I've flown four of them now and they work great......my last flight was a 6 ounce GPS tracker with 1 pound of lift on the nozzle. It went up over 103,600 feet which is quite high for such a small balloon. With 9 pounds of lift I made it to 93,000 feet back in August with one of these....13 pounds of lift made it to 77,000 feet.

8470. Static Pressure test on 100G balloon

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-13 00:13:25 UTC
From: Jerry Gable
Topic: 8470 Message: 8470
Attachments: 1 described; binary payloads are missing from this source WARC

I have my differential pressure transducers, 100G balloons, and a way to measure the balloon diameter so I did my burst test on a 100G balloon today.

I have attached the graph but here it is if it doesn't make it:
http://dl.dropbox.com/u/9446302/BalloonBurstTest1/100G%20Balloon%20Graph.jpg

And here is the spreadsheet:
http://dl.dropbox.com/u/9446302/BalloonBurstTest1/Balloon_1_100G.xlsx

My setup to measure the diameter was 2 laser pointers and a digital protractor. Point the 2 laser pointers at the outer edge of the balloon from a known distance, add some simple math and you have the volume. My fill rate was constant (After the initial pause at the beginning) and the measurements look like they were surprisingly close.

As you can see this one started with a high pressure that dropped quickly followed by a slow decline. At the end it started back up slightly but the pressure was pretty flat for most of the time at just under 0.03PSI.

I am still looking for a building to do the 600G balloon in. If you know of a place around Phoenix let me know.

Jerry

Joe,
Your calculation was very close. So what is your formula for the different balloon sizes?

One thing that I will point out thought is we all thought the pressure would rise significantly as we approached burst and that doesn't appear to happen.

I think the reason that diddn't happen was because of the small size
of the balloon. I suspect that the effect will be more pronounced as
you get larger and larger.

8474. Film on Corona

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-13 18:34:27 UTC
From: L. Paul Verhage
Topic: 8474 Message: 8474

I'm reading about the Corona spy sats. They initially used the same photographic film that was used in the spy balloon flights over the USSR. They discovered after several flights that the film broke a part into fragments iin space, but was fine at 80,000 feet. The outgassing in the hard vacuum of space was significant, but not an issue in near space.

I would agree Joe. I also will add the temperature, possibly inflation rate and other factors are not being re-created on the ground.

We do have two separate data sources that do show the increase in pressure prior to burst on the 1200gr balloon, so we know the constant decrease, lull and increase in pressure are valid. I have several 600gr balloons to fly this fall and wondered if we would see the same effect as the 1200gr balloons. The graph by Jerry points out that this phenomenon with the 1200gr balloons may become much less with smaller balloons to the point of no-existing with the 100gr balloons. I suppose we will fly one in non-venting mode to plot the pressure to a typical burst flight.

I have found a little quirk in CHDK
scripting that will error & halt a script.

You cannot put a REM after a PRINT statement.
The REM has to be on a seperate line.

Anyone know of any other quirks?

Ok, Bummer

The real simple one we got working the one with the top command?

Havent quite figured out why tho it runs backwards regardless of what order the time is in. if there is 10000 and then 5000 it still only records 5 sec and pauses ten, I swither the numbers around and it still records 5 and pauses ten.

I have had the other scripts do a full 30 minute recording, but not loop back.

I'll get this eventually. I may wear out the usb jack in the process tho he he he

Joe,

Get the program UBDebug!
Run & debug your scripts without loading them on the camera.
I posted the link for Paul, but haven't heard if he used it or not.
It's a real time saver!

Oops Missed that!

I had help with that math, But this is what came out of it.

t = 1 mil = 1/1000 of an inch. Is that what you mean?

1/1000" = 0.0254 mm

Assuming D is 13m after pressurizing

P_y = 4 * 0.0254 * 16.6/13000 = 0.00013MPa or 0.13kPa or 0.019psi

If it is 1/4 mil, P_y is 0.0325kPa or 0.0047 psi

Now this is where I needed a more accurate gauge thickness measurement,
Remember I asked on the list if someone could get a as accurate as
possible micrometer measurement of a piece of balloon when stretched to
it's limit?

I lost this number, I did have it at one time when we ran the tests on
the machine to get the balloons tensile strength number. which a few
years ago came in as
Tensile Strength of the material that is the skin of the sphere, = 16.6 Mpa

Now as can be seen if the envelope is thicker or thinner than 1/4 mil at
burst it will change the pressure number. I in the back of my mind
remember 1/4 mil as being this number.

Soooo,, Now for the varying sizes, the numbers were crunched above for
the 3000 gram balloon, the other sizes the failure pressure for a 9.44m
diameter sphere will be 1.38 times higher than that of a 13m sphere.

Then someone sent me this below,,,,,, wow Looks like Greek!

Total force on shell = P*A = P*?D^2 /4

Length of shell resisting force = ?*D

Force per unit length of shell = P*D/4

Failure strength per unit length = t*F_y

Pressure at yield, P_y = 4*t*F_y /D

t = thickness of shell

Fy = yield strength

D = diameter

I'll have to study Joe's formulas and see if I can figure them out. It looks like they are related to the formula that I found.

I did come across this formula for the pressure in a bubble. P=4*gamma/R where P=pressure, R is the radius and gamma is the strength of the skin.

If you use the numbers in my 100G spreadsheet and extract the gamma for one point and then use that gamma on the rest of the points it is surprising how close the curve fits the measured, from the initial peak pressure all the way down to where the curve turns up.

What that tells me is this formula holds for balloons as well as bubbles. The exception is when you approach the maximum stretch of the latex the "gamma" increases.

In Joe's Formula, the gamma is "thickness * Yield strength". It uses D instead of R but that is just a scaling issue with gamma.

Now assuming that all balloons have the same latex properties (thickness, stretch, etc) we should be able to predict the internal pressure pretty accurately using this and Joe's formulas below. I just want to try another size to see if it correlates. I also want to do more 100G balloons to test the consistency.

One thing that I would like to predict is the larger balloons will not have a big low pressure region in the middle. I believe as the balloons get larger the upturn at the end will get smaller. But I have been wrong before.

isn't this crazy!

What camera do you have?

I installed the latest and greatest CHDK stuff. No difference.

Anyone else with a A560 care to try these scripts and see if it works
the right way for you?

Remember these are NOT pictures, the camera is in Video mode.

Maybe I missed it, but why the press and release command?

```
press "shoot_full"
release "shoot_full"
sleep 10000
```

I think most times scripts use the _shoot_ command. The press is good when the button has to be held down while other buttons are pushed. After the press command, you have to use the release command to "take your finger off the button".

Joe,
By pressure in the middle, I meant the pressure curve during inflation, not the middle of the balloon.

It did the same in my camera as yours.
Seems it needs a little sleep at the beginning.

Try this one, it works...

```
sleep 3000
click "shoot_full"
sleep 10000
click "shoot_full"
sleep 5000
click "shoot_full"
sleep 10000
click "shoot_full"
end
```

I'm using an SX-200is camera.

This will also do the same...

```
sleep 3000
shoot
sleep 10000
shoot
sleep 5000
shoot
sleep 10000
shoot
end
```

Joe,

It looks like without the sleep command at the beginning the camera needs a little time to stabilize. It is skipping over the first few lines of the script and starting at the part of the script that is at the 5 sec interval. So it throws off the whole sequence.

73 Harry

Because this is in Video Mode. and when you press the shutter button
it starts the record and then when you press it again it stops it.

This is weird.

Ok what happened with that one is:

5 sec record
10 sec pause
then record started again but never stops

tried

```
sleep 30000
click "shoot_full"
sleep 10000
click "shoot_full"
sleep 5000
click "shoot_full"
sleep 10000
click "shoot_full"
end
```

No difference except to took 30 seconds of course to get started. other wise still the same

5 sec record

10 sec pause

record starts and never stops.

Joe,

Are you sure you have the right build for the firmware
version of your camera? There are two available.

v1.00A
v1.00E

How did you determine the version on yours?
Here's a utility to make sure...

Harry's script should result in three recordings of 15 seconds with pauses of 8 seconds.
 Joe's camera misses the first "shoot_full" and as a result has two recordings of about 8 seconds with pauses of about 15 seconds before it starts a final recording that never sees a "shoot_full" to stop.
I'd suggest adding on "shoot_full" just before the for-next loop and see what happens.
Howard

Hi Howard,

There's something weird going on with Joe's camera or the build of CHDK he's using. Every script I've set him, that works on mine, screws up. I also noticed it missing the first part of the script on his. I suggested a longer initial sleep to let the camera stabilize, but that failed also.

Hello All,,

Well for those that have been following the thread of getting a script to run videos with the Cannon CHDK scripts i finally got it to work and use all 16 Gig of the SD card for recording!

It took thinking that the camera is ultra slow and stupid and to mimic what your fingers do in every way and even slower.

Attached is a script that will make the Camera take 8 fifteen minute videos. (2 hours of recording time),

Here is the script, just one segment and I just copied this eight times in the file.

```
sleep 3000
press "shoot_half"
sleep 1000
press "shoot_full"
sleep 1000
release "shoot_full"
sleep 1000
release "shoot_half"
sleep 900000
press "shoot_half"
sleep 1000
press "shoot_full"
sleep 1000
release "shoot_full"
sleep 1000
release "shoot_half"
sleep 3000
```

But taking it very slow was all it needed to do,

After hearing Bill's presenrtation in 2008, I've wanted to get a SPOT. Aftyer getting it set up, I took it to work this morning. I've attached the two waypoints that were sent to the SPOT satellite. The receiver/transmitter was sitting on the dash of my car, so only two messages got out. I'll be interested in sending it up on a near space flight later this year.

It IS actually quite simple.

I took your design more or less and just pushed it up a bit since I did not have the parts to make it fail safe at low altitudes with the baroswitch components. So I just took the basic design and exagergerated the motion soo far that it needs to rotate Like120 degrees or so to actually release. so any very short duration lapses in tension and it wouldn't have enough time to release. Plus we made the tension to be just barely open. any tension at all and it remains closed. we figure if it gets stuck, the PBC will shake it open at worst case. In addition the shock absorber keeps tension on it no matter what or at least until there is absolutely no pull left (Popped Balloon)

I wonder in our lower altitude balloon experiments how big a mylar balloon would have to be to become a decent passive reflector.

Like the Colorado balloon Boy saucer balloon,,, if made as a ZP balloon, I wonder what altitude it might have gotten to, an it was pretty big, I wonder what freqs could have reflected?

A Dish antenna that is a screen only needs to have wire spacings of a tenth of a wavelength. so i would think something that big should reflect any vhf/uhf signal.

I remember in the suburbs of chicago when i first got licenced, we all used to bounce 2 meter sigs off all the jets coming in and out of Ohare...this was in the 70's

hmmmmm, do we see a trend here with me and Ohare?

The SPOT looks interesting. It has a pretty low ceiling. What happens when you go above that?

[Attachment(s) from L. Paul Verhage included below]
After hearing Bill's presenrtation in 2008, I've wanted to get a SPOT. Aftyer getting it set up, I took it to work this morning. I've attached the two waypoints that were sent to the SPOT satellite. The receiver/transmitter was sitting on the dash of my car, so only two messages got out. I'll be interested in sending it up on a near space flight later this year.

Bill will know better. I believe it will come back online once it drops
below 60k feet.

I'll find out for myself in a few weeks.

Paul,
Let us know what it does at altitude. Acording to their website the Altitude range is pretty small. Max Alt is listed as 21,320 ft. As long as it turns back on when it gets below this altitude it would be a great way to find the payload in back country.

Any ideas on how to encourage it to land antenna up? A short, wide package (say 8x8x2tall) would probably give it better than 50% chance of landing that way.

Bill said he got a position report when it was up sidedown.

It will send position reports out every ten minutes on descent, so you'll get a track of the landing. Let's see, 10 minutes reports at 1,000 fpm descent, you could potentially get your last report 2 miles above the ground. On average, more like 5,000 feet AGL. What kind of a foot print does that leave?

I wonder if it could be packed in a seperate module suspended well below the last one by a single cord. If that module was a lot wider than tall, it may be resistant to tipping over.

Optionally, perhaps it could be placed inside a sphere that was bottom heavy.

Or it could be suspended on a craddle inside a module that is rotated to horizontal by a servo after landing.

What about putting the SPOT inside a spherical container inside a box. Regardless of how the box lands, the sphere inside is free to rotate to heavy side down, like a hamster ball.

I think I like the last idea.

But the hamster ball will only work if the ball and box are
frictionless. otherwise it could still end up up-side-down if it's
stuck trying to roll into a side or corner of the box.

I think a separate container is probably a good idea. They talk about the need to keep it at least 12" away from any other GPS to prevent interference.

As far as keeping it upright, how about a gimble mount, a couple of servos and an accelerometer? Might as well over engineer this:)

Wait wait....
I'll go up and keep the unit flat!!!
;)

The roller inside a roller sounds pretty simple. I like using the seperate module, however.

OK regular alkaline couldn't do it, they ran out of gas before card
was full. So just wiped the card clean and started over with a set of
Lithiums in the camera.

and way cool gang, it works and works perfectly it ran till the card
was full, 9 - 15 min loops and a 5 min leftover small one.

looking at the card it recorded till there was 320 K left open, thats it,

so on a 16 Gig card we got 140 minutes of recording!

Cool

I attached for anyone that wants it the bas file that Harry Made,

Enjoy!

how about a like gyroscope gymbal, like a ship board compass? an
assembly like a gyroscope with the innerds base heavy, then it
absolutely doesn't nedd to land any direction and up will be up.

8525. Re: [GPSL] SPOT

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-16 22:03:45 UTC
From: Jerry Gable
Topic: 8513 Message: 8525

I think a fairly long, skinny box (think of a short shipping tube) with a rod on bearings through the center and the Spot slightly below center would do. The only way it wouldn't face up is if the box stood on end and that is unlikely.

how about a like gyroscope gymbal, like a ship board compass? an assembly like a gyroscope with the innerds base heavy, then it absolutely doesn't nedd to land any direction and up will be up.

From: wb8elk@aol.com
Topic: 8513 Message: 8526

The Spot works up to about 60,000 feet....higher than their spec of 27,000 feet.....it does not report the altitude though. It usually comes back on during the descent after falling below 60k ft....but sometimes does not report until after it has landed.

After hearing Bill's presenrtation in 2008, I've wanted to get a SPOT. Aftyer getting it set up, I took it to work this morning. I've attached the two waypoints that were sent to the SPOT satellite. The receiver/transmitter was sitting on the dash of my car, so only two messages got out. I'll be interested in sending it up on a near space flight later this year.

From: wb8elk@aol.com
Topic: 8513 Message: 8527

I've had the Spot successfully report it's position while upside down in the mud after landing. I'm working on a "hamster ball" inside container for it though for this Fall....actually my version is two concentric rings with pivot points inside a styrofoam container with a weight on the bottom of the Spot....kinda like that three axis simulator that they do in Space Camp.

Bill said he got a position report when it was up sidedown.

It will send position reports out every ten minutes on descent, so you'll get a track of the landing. Let's see, 10 minutes reports at 1,000 fpm descent, you could potentially get your last report 2 miles above the ground. On average, more like 5,000 feet AGL. What kind of a foot print does that leave?

I wonder if it could be packed in a seperate module suspended well below the last one by a single cord. If that module was a lot wider than tall, it may be resistant to tipping over.

Optionally, perhaps it could be placed inside a sphere that was bottom heavy.

Or it could be suspended on a craddle inside a module that is rotated to horizontal by a servo after landing.

What about putting the SPOT inside a spherical container inside a box. Regardless of how the box lands, the sphere inside is free to rotate to heavy side down, like a hamster ball.

I think I like the last idea.

I usually do put the Spot in a seperate payload...usually the last thing on the flight train.

Yes....I'm doing my inside support as two concentric rings with alternating gimbals and a weight on the bottom of the Spot...that way no matter what the landing orientation is, it will always point up....probably not worth doing as it does seem to work at odd angles and even upside down....but it would increase the signal if it was able to point directly up at the sky. I'm mostly doing this so that it will work while floating at sea when I start the trans-Atlantic flights in December since upside down in salt water probably wouldn't work very well.

I wonder in our lower altitude balloon experiments how big a mylar balloon would have to be to become a decent passive reflector.

Like the Colorado balloon Boy saucer balloon,,,? if made as a ZP balloon,? I wonder what altitude it might have gotten to,? an it was pretty big,? I wonder what freqs could have reflected?

A Dish antenna that is a screen only needs to have wire spacings of a tenth of a wavelength.? so i would think something that big should reflect any vhf/uhf signal.

I remember in the suburbs of chicago when i first got licenced, we all used to bounce 2 meter sigs off all the jets coming in and out of Ohare...this was in the 70's

hmmmmm,? do we see a trend here with me and Ohare?

Balls don't roll easily on most terrain - even the seemingly featureless planar landing sites typical of E. Colorado. It's the prairie grass, y'see. Students who've flown "roversats" on our strings have learned that the hard way.

Of course, you might get lucky and land on a paved highway ...

The minimum size for an effective reflector is 1/2 wavelength. So that
134-ft diameter bag COULD have worked down to 80m - but the small aperture
and path loss woulda pushed even a 60 dBm terrestrial sig down into the
mud (QRN). I expect that a decent 2m rig coulda worked fine, IIRC.

I got my ticket when I was 16, but that was before Echo launched, young man :=). But my station consisted of a Heathkit AR-1 receiver with a BC-453 Q-5er and a DX-40. I prolly coulda heard Sputnik just below 15m then, but I was 3 years too late :=(.

8537. Re: [GPSL] Static Pressure test on 100G balloon [1 Attachment]

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-17 02:58:29 UTC
From: Mike Manes
Topic: 8470 Message: 8537

Hi Jerry,

Great experiment.

What's worrisome is that we typically fill for a 100K' burst, where the balloon volume is 100X that at sea level. So for that 100 gm baq, that would mean a fill volume of 75/100 = 0.75 cuft. At that volume, the pressure is on the order of 3 times that just prior to burst. And at 7.5 cuft, which would be the volume at about 50K', the pressure has only dropped to a little under 2x the burst pressure.

That bodes ill for using a sharp rise in pressure to detect an impending burst. Now that model may not play out with a larger balloon, so I look forward to your 600 gm results.

For an interior fill site, you might see if you could get into a high school or college gym or field house - or just do it outside on a nice calm morning.

Date: 2010-09-17 17:36:32 UTC
From: Keith Kaiser
Topic: 8539 Message: 8539

I see a lot of references to flights that I have not been asked to post on the announcement page. For example iHAB has now announced an Oct. 2 launch which I know nothing about.

My request to all of you is this. If you see reference to a flight that has not been posted on arhab.org please send them a request to fill out the form and announce it to the rest of the world. By far our announcement page is looked at by more people then see just the ballooning Yahoo group or any other single group online. So best coverage and best for us is if they send me the post.

For reference, here are the key web sites;
Announcements: http://arhab.org (select the tab) or direct at;
http://www.arhab.org/ARHABlaunchannouncements.html

The form they should fill out is at; http://arhab.org on the appropriate tab.

Thanks for your help on this guys.

If you have any questions, please send eMail direct to me, off any given list.

From: BASE
Topic: 8540 Message: 8540

Dear friends,

The 50th flight in the BASE program from DePauw was successfully completed today. Launch occurred at 10:03 am EDT from the roof of the Julian Science Center on the DePauw campus in Greencastle, Indiana. Maximum altitude was 88,600 feet. We had a nice visual sighting on the landing for the last three minutes or so of the flight. Landed in a vacant horse corral southeast of Franklin, Indiana near I-65. Our new experiment successfully recorded good data throughout the flight.

I heard the multi-mode transmitter operating on 147.45 MHz throughout the flight, but did not have any decode program running. I would appreciate direct contact from anyone that was able to copy and decode the transmissions.

The next flight will be next Saturday from the Centennial Campout of the Heart of America Council of the Boy Scouts from Camp Naish near Bonner Springs, Kansas.

Thanks for your support,
Howard, KC9QBN

8541. Comparison of 3 100G balloons

I wasn't going to post this but I find it fascinating.

I was prepping the equipment to pop a 600G balloon next week and popped 3 100G balloons to test it. The graph of the 3 balloon's pressure is attached. The fill rate is much faster than before but it was the same for all 3 of these balloons.

What is amazing is how close the curves follow each other. The burst times are significantly different and I don't understand that. These are surplus balloons so maybe that explains it.

Anyhow, I think I am ready to try the big balloon next week.

Two of the balloons exhibit a hint of increased pressure prior to burst.
I will be curious if the 600gr balloon shows a more pronounced increase
as we have seen in the 1200gr. balloons.

Very interesting tests, I am enjoying your exploration into this area
very much!

8548. WB8ELK pinhole floater on the ground now

Date: 2010-09-20 07:48:00 UTC
From: wb8elk@aol.com
Topic: 8548 Message: 8548

After a very interesting 4-hour flight, the pinhole floater is on the ground near Blountsville, AL....about 35 miles SE of the launchsite. Check out the graph below the map on: http://spacenear.us/tracker and you'll see an ascent rate and descent rate curve that you don't get to see very often. Apparently the 1/16" pinhole is too large for a 600 gram balloon (the main purpose of this flight). I made it up to about 39,000 feet and came down almost the same descent speed as the very slow ascent.

It should be quite a sight to see it standing out there with the balloon intact in a cow pasture when the Sun comes up....hopefully someone other than a cow will see it.

- Bill WB8ELK

I would venture a guess here that the 600gr balloon may never reach a near-zero pressure state internally, and therefore will have a fairly constant leak rate throughout the flight. The 1200gr and possibly 3000gr balloons likely do reach a near zero pressure state (or less) and therefore "float" more since the pressure is less and the pin hole constant,outflow will be less. I think the 600gr will need the valve system we've both been toying with for a good float and return.

I hope you are right about the cow pasture, I zoomed in on the last coordinates shown on tracker using the satellite view, and it looks like you might have some tree challenges! :)

Enjoyed it Bill! Great flight and tracking!

I am going to help do chase and recovery and I see that Keith has added my name and call to the Chase/recovery list. Is anyone launching going to use a Garmin Rino. I also saw a prediction for the landing site for those balloons and I do not seem to find it now. Where did it go or is my old age really getting to me? Thanks Mike KDØFW

I've added the NSV flight projection link to the announcement page at;
http://www.arhab.org/ARHABlaunchannouncements.html

No Rinos will be hurt during the flight of these balloons...or used for that matter.

Will anyone have tracking equipment they can set up at my launch site?

I have a mobile set up that won't work well for scouts.

My equipment is packed in pretty tight in my truck and wouldn't work well for the scouts at all. Sorry Mike

8554. New Balloon Group - LVL1 White Star Balloons

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-22 17:12:45 UTC
From: dbowen1
Topic: 8554 Message: 8554

Hi Guys,
     I'd like to introduce a new group to the balloon arena, the LVL1 White Star Balloon team. LVL1 is a new Hackerspace in Louisville KY, with about 60 members, see http://lvl1.org. As hackerspaces often do, they had many a show-and-tell event to share your fun personal projects. I've participated in these, and as I gave them tales of trans-atlantic ballooning while waving a Spirit of Knoxville flight computer board in the air, and they were hooked. They are quite a talented bunch, so I've not dissuaded them from their goal to beat the SNOX distance record this winter.

The plan is such: A simple latex or two this fall to work out the kinks of ATC and the launch team. Then 4 to 8 ZP flights from Dec 2010 to April 2011.

Aviation safety is a big concern for TA flights. Cornell will be flying this year strictly above 60k ft to stay out of controlled airspace. We can't afford a balloon that can do that - 100,000+ cu ft. We plan to be right down among 'em in the Jet Stream, with a ~1000 cu ft ZP, much like the original SNOX TA balloons from Mark Caviezel. To ensure airplane safety, we will be providing the NAT-Tracks ATC with a very reliable stream of position reports. We will require two-way radio comms at all times with the balloon, to allow a dead-man switch cutdown. If the balloon doesn't hear from us frequently, it will cut itself down. If we stop receiving telemetry from the balloon, we stop pinging the balloon from the ground, which initiates cutdown

We are not going to use HF telemetry for the primary link. HF requires an extensive volunteer receiver network, and complex server side software that we just don't have the time to develop this year. We will be using a satellite data modem for the telemetry and command uplink. They have come down significantly in price, and are at the point of being an actual affordable option, quite comparable in cost to a kit 2m APRS transmitter. The Digi m10 is a mere $149, for example, and data service is estimated to be about $50/month through Orbcomm. The electrical specs are quite manageable on the m10: 5w transmit power, 1.5A @ 12v for maximum of 4 second TX bursts. Orbcomm requires only a VHF dipole or similar home-brew antenna.

Also, we've found an ebay auction selling some older satellite data modems for Orbcomm, which we're looking into:

http://cgi.ebay.com/NEW-OrbComm-Stellar-ST2500-Satellite-Data-Communicator-/160480811653?pt=LH_DefaultDomain_0&hash=item255d66da85

They're really heavy and power hungry, the bare circuitry is spec'd to weigh 7.5oz, and they're 2.8A @ 12v. BUT, they cost $50 each, and he has a bunch of them. I thought I'd let you all know, as it's quite a bit more functional than the findmespot for telemetry and uplink.

Thanks,
Dan

Way To Go Dan with LVL1 Hackerspace

it took me ~3years to get the idea to catch here in St Louis

maybe you can explain hackerspace to me sometime.... the St Louis Area is covered with Ham clubs, Linux SIGs, Unix users goups, robot clubs, CNC clubs on and on, and then last fall some guys decided to start their own "hackerspace" i don't see anything they have acheived but water down other groups by pulling bring minds from other cool projects. and i'm not sure they have done anything in nearly a year except grow fast in member numbers.

But i guess that is just how politics in St Louis goes 93 incorporated(each with mayor and councils) Cities in just St Louis County
there are dozens if not 100s+ repeaters on VHF & UHF (ARRL's idea of "regional PL" doesn't work here)

best of luck,
Carlton

From: Mike Manes
Topic: 8453 Message: 8556

Interesting, using the focus assist lamp as an output device under
script control. The EOSS SamCam2 uses the status LEDs near the
viewfinder to detect when the camera shoots. This sig goes to a
PICAXE8 that drives an elevation servo to next of 3 positions:
down, horizon and up.

What would be cool would be some means to set up a binary input
to the camera that could be read by the script - one that didn't
involve bringing out button contacts, of course. Maybe via the
USB port?

8557. DX barrier of 500 miles from a balloon has been broken

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-25 19:53:32 UTC
From: wb8elk@aol.com
Topic: 8557 Message: 8557

I successfully copied the 20 milliwatt DominoEX22 transmission (as well as a bit of the Hellscreiber) from the W9YJ BASE 51 payload (W0A-11 on APRS) today that was launched from the Boy Scout event in the Kansas City area. I was able to hear the signal on 147.453 USB well enough to get sequence number 166 at around 18:00 UTC just prior to the burst as well as a couple of other partial frames of data....I had copy from 1758 to 1804 UTC on it...burst occured around 1801 UTC. The APRS callsign on this balloon was: W0A-11.

Distance to the balloon was about 506 miles. I couldn't hear it on FM, but SSB was quite a nice signal for a couple of minutes.

I was using a 4 element beam on a 10 foot tall tripod with a TS-2000 for the receiver....however, it really is equivalent to a 510 foot tall antenna tower since I'm 500 feet above average terrain here on my mountaintop QTH.

W9YJ (W0A-11 BASE 41) DominoEX22 reception from WB8ELK in Falkville, AL (34.4086 -86.813) at 1758 to 1804 UTC - burst occured at near 1801 UTC....battery voltage was 5.67 volts and internal temperature was -7 deg C....the lat/lon was somewhat garbled, but comparing it to the W0A-11 APRS data the position was: 38d 53.49m 94d 02.38m at 95,712 feet.

Murphy and his laws were out in force for my 600G balloon burst today. What could go wrong today did.

1. The 35mW green lasers I was using to measure the balloon's diameter were not visible once the full sun started to hit the balloon.

2. A 600G balloon gets really big (see attached image). Even a slight wind pushes it around. As the wind picked up it eventually pulled it off of the PVC fill pipe and it slowly floated away to the west (~100 SCF of He gave it just enough lift).

3. Oh well I at least would have some data at for the first part of the fill. When I got home I found out I had forgotten to enable the channel on the logging software. I have 46 minutes of 0.0v on 8 channels. Why would anyone write software that defaults to all channels off and doesn't show anything while it is recording?

So my experiment will have to wait until my next launch. I plan on measuring temp and pressure inside the balloon on that flight.

Jerry

Bummer, Jerry,

Screw-type stainless steel hose clamps work quite well to secure the neck
of a balloon to the fill tube; we use two, just for belt and suspenders.

If you're filling at sunrise on a clear morning, you could use the shadow
of the balloon on a vertical wall to measure its diameter. The parallax
error will be negligible. Or you could use a spot light with measured
between it and the balloon and the balloon and the wall, plus a little
trig, to accomplish the same end.

I agree on the stainless Steel hose clamp. thats all we ever use. Like Mike on small flights we use 1 clamp, on heavier flights like 6 pounds of lift or more we use 2. I cringe every time I see videos of other balloon groups using duct tape anywhere on the balloon for any reason. Duct tape is yes very sticky, and will stick to almost anything. BUT it looses it's grip very fast on anything that can stretch. It acts just like those "Command" hangers from 3M. if they aren't stretched they hold tons of weight. But stretch the substrate and they loose all their grip and fall off. Quite ingenious actually. But very bad for wanting to attach anything to a balloon.

And Mikes suggestion of the sun up shadow, or a simple floodlight is a great suggestion.

This past weekend, I launched or help launch two balloons. One (mine) I used a hose clamp like I always do. The other we used duct tape, it did a great job, I saw no indication of it pulling away. I will admit I think the duct tape is more work, and messy, but I saw nothing that said it wasn't a viable way to do it.

Duct tape can work, if done carefully and the surfaces you're dealing with aren't damp and/or cold. However, this can happen if one or both conditions are met:

http://www.youtube.com/watch?v=FE8SPugjtwM

This was the second time this happened to us, the first was in 2001 and we thought it was a fluke. Since this instance, we've gone to hose clamps (the thumb-screw pop-open type so we have one less tool to fumble with) and we pull on the neck firmly before filling to assure ourselves the clamps are tight enough.

We had a screw type hose clamp holding the balloon on. At the time it pulled off it was dragging the table and a cement block around pretty easily. I was holding the table down so and the neck was 2-3x its normal length. It was only a matter of time before the balloon hit something sharp enough to pop it or it ripped off the neck.

The lasers were easy to see in noon day sun but the morning sun reflecting off the white balloon was too much.

Jerry

I agree on the stainless Steel hose clamp. thats all we ever use. Like Mike on small flights we use 1 clamp, on heavier flights like 6 pounds of lift or more we use 2. I cringe every time I see videos of other balloon groups using duct tape anywhere on the balloon for any reason. Duct tape is yes very sticky, and will stick to almost anything. BUT it looses it's grip very fast on anything that can stretch. It acts just like those "Command" hangers from 3M. if they aren't stretched they hold tons of weight. But stretch the substrate and they loose all their grip and fall off. Quite ingenious actually. But very bad for wanting to attach anything to a balloon.

And Mikes suggestion of the sun up shadow, or a simple floodlight is a great suggestion.

8566. BSA Centennial Balloon Launches

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-27 17:46:42 UTC
From: Keith Kaiser
Topic: 8566 Message: 8566

Thanks to Howard and Paul we were able to launch three HAB's this past Saturday from the Heart of America Councils BSA Centennial Campout. Two of the balloons Howard's and my own we launched just after 11a.m, a heavy storm was on its way in and we wanted to get out before it arrived. Howard was able to launch at about 11am, I got off the ground about 11:20am, with the help of about 30 boys from Troop 24.

Later after the storm didn't appear, Paul was able to launch his balloon about 1:30pm. It was just starting to rain when it left the ground, and by the time I got back to my computer to track, it was poring. When I say pouring I mean pouring, the rain came down in buckets. But the balloon was up.

11,500 boys and adults took place in this weekends activities, everyone I talked to says they saw at least one, in some cases two and a few all three balloons. Surely this is the largest attended HAB launch in history.

Two of the balloons have been recovered, the third is in a known location. But the rain had moved East by touchdown and the balloon landed in the middle of the largest corn field I have ever seen. Deb and her team of chase/recovery people did a superb job but I told them to go home, we'd pick it up another (dryer) day.

I have no way to thank all the people who lent support for this activity but I want to single out Howard Brooks for driving all the way to Kansas from Indiana. And to Paul for driving all the way in from Topeka as well. Both guys had to put up with remote parking, bus drivers who got lost and thousands of boys asking questions like what is the balloon made of. It's also very important that I thank the chase/recovery teams of Jerome Tonneson, Mike Bogard and his girl friend Deloris, John Morell, Jim Bair, and of course their fearless leader and my most wonderful wife Deb Kaiser. If I forgot anyone, shame on me but please know you too are being thanked.

The balloon slid of the PVC pipe cleanly. The clamp stayed with the balloon. I thought the clamp was tight but I guess not tight enough.

ahhhh, yeah thats why we use two, and soo tight you think the clamp
is just about to strip out. the latex is squeezing out in the open
threads of the clamp.

We cut a ring made from a PVC coupler and glued it to the end of the fill pipe, then clamp below that. That keeps the clamp from sliding off the end. Before gluing that ring on, we also dipped the end of the PVC into a can of Plasti-Dip which probably would be enough by itself to prevent slippage.

It was good fun.

It looks like I'll be doing a launch for Washburn in October (latter half). I'll let everyone know the day and I'd like to invite everyone out to chase (cuz I'm going to need chase help).

Keith,
I truly enjoyed the day with the Scouts. Most of my help came from Troop 55 of Lawrence, Kansas. I had a few Scouts that made friendly bets (for animal crackers) about the landing points for the balloons.
I also want to thank Deb and her trackers. Mike, KD0FW, did a fantastic job of collecting my system and we have some very good data for our student research project at DePauw.
Bill, WB8ELK, already shared his success in copying the DominoEx transmission in Alabama. Did anyone else copy the 147.45 MHz signals? I am especially interested to see if others had trouble with copying the lat/long/altitude information.
I was surprised that I could get a 600 gram balloon to 95,700 feet while carrying four pounds of payload. That is the highest that our program has achieved for that size balloon.
Looks like we'll fly on Thursday (I'll get the form filled out).
Thanks for your support,Howard, KC9QBNBASE-DePauw

How much lift was at the nozzle of the balloon?

IE; Payload weight+ positive lift in other words how much lift was at
the neck of the balloon with nothing attached?

Joe,
That question is not easy to answer exactly. The fill was done outdoors. The balloon lifted the dead weight of six pounds, with the filling hose still inside the neck of the balloon, which would lead me to believe that there was a little more than six pounds of neck lift. However, the wind was beginning to be significant (approaching 10 miles/hour), and I am confident that there was some wind induced lift. I've never done the calculations for wind lift on a 600 gram balloon.

Duct tape sticks to water, which doesn't stick to much a'tall. So if you're using duct tape to secure your balloon to a fill tube in a humid environment, the adiabatic cooling of the expanding fill gas can produce condensation or flat-out frost - and that'll do in the duct tape's adhesion. I recall seeing a video (with bleeped audio) of rainy (partial) fill using duct tape in the rain.

Hose clamps are inexpensive and quite reusable - and a whole lot cheaper than a bag of He that goes AWOL. Duct tape works great on dry surfaces.

Check this out,

First I feel still funny posting stuff like this that has absolutely
nothing to do with GPSL here on the GPSL list. How is the groups
transitions coming along?

Anyway check this out It can carry a 500 Gram camera aloft. It's neat
but when you get to the bottom and see the pricetag, LIKE WHAT!?

http://www.gizmag.com/flying-lift-camcorder-system/16477/?utm_source=Gizmag+Subscribers&utm_campaign=36ae023612-UA-2235360-4&utm_medium=email

8578. List update

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-28 14:41:33 UTC
From: Mark Conner
Topic: 8578 Message: 8578

Joe and others' comments prompted me to make a quick update on this. Basically I haven't had much time to pursue this, and there's not a clear consensus. The two options that stand out are keeping things as is, or starting a new group for general ARHAB discussions at Google. I'm somewhat afraid that the latter will die as most people are comfortable here and the inertia of signing up for a new group at a new site may be more than the majority of people are willing to do.

I would like to update the GPSL front page for the group here, but it looks like Yahoo has an impending redesign coming for its groups functionality. I think that should wait until Yahoo makes their changes, as it might have to be done again.

Keith,

I truly enjoyed the day with the Scouts. Most of my help came from Troop 55 of Lawrence, Kansas. I had a few Scouts that made friendly bets (for animal crackers) about the landing points for the balloons.

I also want to thank Deb and her trackers. Mike, KD0FW, did a fantastic job of collecting my system and we have some very good data for our student research project at DePauw.

Bill, WB8ELK, already shared his success in copying the DominoEx transmission in Alabama. Did anyone else copy the 147.45 MHz signals? I am especially interested to see if others had trouble with copying the lat/long/altitude information.

I was surprised that I could get a 600 gram balloon to 95,700 feet while carrying four pounds of payload. That is the highest that our program has achieved for that size balloon.

Looks like we'll fly on Thursday (I'll get the form filled out).

Thanks for your support,
Howard, KC9QBN
BASE-DePauw

Date: 2010-09-28 19:59:00 UTC
From: L. Paul Verhage
Topic: 8580 Message: 8580

It looks like we will launch from Topeka on Oct 16 with the 23rd as a backup.

I'll post information as soon as I get the details.

I'm looking for anyone in the area who would like to help out with. Especially with tracking and recovery,

Thanks

My filling nozzle has a groove in it.....I just tie a string around the neck at the groove location and it holds just fine...tested to 25 pounds of lift or more over the years.....I add a strip of duct tape around the bottom of the neck just to make sure. But if your fill nozzle does not have a groove in it, then duct tape alone will not be a good idea...My true favorite is as described below but I haven't used the method below for awhile since I misplaced the NWS device a few years ago during a move:

The NWS balloons also have a groove in their filling nozzle (a nicely machined aluminum affair)....they hold it on with what is essentially a wire loop (about the diameter of a coat hangar) with two ends....you squeeze on the ends and the loop gets bigger...release the wire ends and the loop contracts....it works great....wish I knew where to buy more of these...I only have one that was given me by a NWS balloon launch facility. This is the easiest and quickest way to hold a balloon to a fill nose....lots quicker and far less trouble than a hose clamp or string/duct tape. If anyone finds something like this at an auto parts store or a hardware store, let me know.

Subject: Re: [GPSL] Murphy helped with the balloon burst test today.

This past weekend, I launched or help launch two balloons. One (mine) I used a hose clamp like I always do. The other we used duct tape, it did a great job, I saw no indication of it pulling away. I will admit I think the duct tape is more work, and messy, but I saw nothing that said it wasn't a viable way to do it.

On Sep 27, 2010, at 8:25 AM, Joe wrote:

I agree on the stainless Steel hose clamp. thats all we ever use. Like Mike on small flights we use 1 clamp, on heavier flights like 6 pounds of lift or more we use 2. I cringe every time I see videos of other balloon groups using duct tape anywhere on the balloon for any reason. Duct tape is yes very sticky, and will stick to almost anything. BUT it looses it's grip very fast on anything that can stretch. It acts just like those "Command" hangers from 3M. if they aren't stretched they hold tons of weight. But stretch the substrate and they loose all their grip and fall off. Quite ingenious actually. But very bad for wanting to attach anything to a balloon.

And Mikes suggestion of the sun up shadow, or a simple floodlight is a great suggestion.

Murphy and his laws were out in force for my 600G balloon burst today. What
ould go wrong today did.
1. The 35mW green lasers I was using to measure the balloon's diameter were
ot visible once the full sun started to hit the balloon.
2. A 600G balloon gets really big (see attached image). Even a slight wind
ushes it around. As the wind picked up it eventually pulled it off of the PVC
ill pipe and it slowly floated away to the west (~100 SCF of He gave it just
nough lift).
3. Oh well I at least would have some data at for the first part of the fill.
hen I got home I found out I had forgotten to enable the channel on the
ogging software. I have 46 minutes of 0.0v on 8 channels. Why would anyone
rite software that defaults to all channels off and doesn't show anything
hile it is recording?
So my experiment will have to wait until my next launch. I plan on measuring
emp and pressure inside the balloon on that flight.

I've shown this before but thought I would again.

We use a PVC threaded bushing with a machined notch and a plastic zip-tie around the balloon's neck. It's easy and has worked well for us. The best part is a loop used to tie off the suspension line is easy to connect, handle a full balloon, tie a safety line and check for lift.

These fit well on a 1200 g balloon and, I'd think, others. If anyone is interested I'd be happy to make and send them one for the cost of the bushing (about $1), shipping and an envelope (a couple of more dollars).

You can see what I'm trying to describe by clicking here<http://s33.photobucket.com/albums/d94/bigheadpete/?action=view&current=IMG_0008.jpg>

My filling nozzle has a groove in it.....I just tie a string around the neck at the groove location and it holds just fine...tested to 25 pounds of lift or more over the years.....I add a strip of duct tape around the bottom of the neck just to make sure. But if your fill nozzle does not have a groove in it, then duct tape alone will not be a good idea...My true favorite is as described below but I haven't used the method below for awhile since I misplaced the NWS device a few years ago during a move:

The NWS balloons also have a groove in their filling nozzle (a nicely machined aluminum affair)....they hold it on with what is essentially a wire loop (about the diameter of a coat hangar) with two ends....you squeeze on the ends and the loop gets bigger...release the wire ends and the loop contracts....it works great....wish I knew where to buy more of these...I only have one that was given me by a NWS balloon launch facility. This is the easiest and quickest way to hold a balloon to a fill nose....lots quicker and far less trouble than a hose clamp or string/duct tape. If anyone finds something like this at an auto parts store or a hardware store, let me know.

This past weekend, I launched or help launch two balloons. One (mine) I used a hose clamp like I always do. The other we used duct tape, it did a great job, I saw no indication of it pulling away. I will admit I think the duct tape is more work, and messy, but I saw nothing that said it wasn't a viable way to do it.

On Sep 27, 2010, at 8:25 AM, Joe wrote:

I agree on the stainless Steel hose clamp. thats all we ever use. Like Mike on small flights we use 1 clamp, on heavier flights like 6 pounds of lift or more we use 2. I cringe every time I see videos of other balloon groups using duct tape anywhere on the balloon for any reason. Duct tape is yes very sticky, and will stick to almost anything. BUT it looses it's grip very fast on anything that can stretch. It acts just like those "Command" hangers from 3M. if they aren't stretched they hold tons of weight. But stretch the substrate and they loose all their grip and fall off. Quite ingenious actually. But very bad for wanting to attach anything to a balloon.

And Mikes suggestion of the sun up shadow, or a simple floodlight is a great suggestion.

Bummer, Jerry,

Screw-type stainless steel hose clamps work quite well to secure the neck of a balloon to the fill tube; we use two, just for belt and suspenders.

If you're filling at sunrise on a clear morning, you could use the shadow of the balloon on a vertical wall to measure its diameter. The parallax error will be negligible. Or you could use a spot light with measured between it and the balloon and the balloon and the wall, plus a little trig, to accomplish the same end.

Murphy and his laws were out in force for my 600G balloon burst today. What could go wrong today did.

1. The 35mW green lasers I was using to measure the balloon's diameter were not visible once the full sun started to hit the balloon.

2. A 600G balloon gets really big (see attached image). Even a slight wind pushes it around. As the wind picked up it eventually pulled it off of the PVC fill pipe and it slowly floated away to the west (~100 SCF of He gave it just enough lift).

3. Oh well I at least would have some data at for the first part of the fill. When I got home I found out I had forgotten to enable the channel on the logging software. I have 46 minutes of 0.0v on 8 channels. Why would anyone write software that defaults to all channels off and doesn't show anything while it is recording?

So my experiment will have to wait until my next launch. I plan on measuring temp and pressure inside the balloon on that flight.

So this brings up a question. How many leave a fitting in the balloon for the flight?

I always tie on the flight string sealing the balloon, remove the fill tube, roll up the neck and tape everything.

Also, I have heard that wire ties become brittle at -55? Anybody seen this issue?

I've shown this before but thought I would again.

We use a PVC threaded bushing with a machined notch and a plastic zip-tie around the balloon's neck. It's easy and has worked well for us. The best part is a loop used to tie off the suspension line is easy to connect, handle a full balloon, tie a safety line and check for lift.

These fit well on a 1200 g balloon and, I'd think, others. If anyone is interested I'd be happy to make and send them one for the cost of the bushing (about $1), shipping and an envelope (a couple of more dollars).

You can see what I'm trying to describe by clicking here

Hi Bill,

I've seen that type of hose clamp used on cars before, like for radiator
and air intake hoses. Might drop in and ask the guys at parts store, or
better yet, a crusty old mechanic who might point you to a make and model
car if the part store clerks are clueless.

If you're filling at sunrise on a clear morning, you could use the shadow of the balloon on a vertical wall to measure its diameter. The parallax error will be negligible. Or you could use a spot light with measured between it and the balloon and the balloon and the wall, plus a little trig, to accomplish the same end.

Murphy and his laws were out in force for my 600G balloon burst today. What could go wrong today did.

1. The 35mW green lasers I was using to measure the balloon's diameter were not visible once the full sun started to hit the balloon.

2. A 600G balloon gets really big (see attached image). Even a slight wind pushes it around. As the wind picked up it eventually pulled it off of the PVC fill pipe and it slowly floated away to the west (~100 SCF of He gave it just enough lift).

3. Oh well I at least would have some data at for the first part of the fill. When I got home I found out I had forgotten to enable the channel on the logging software. I have 46 minutes of 0.0v on 8 channels. Why would anyone write software that defaults to all channels off and doesn't show anything while it is recording?

So my experiment will have to wait until my next launch. I plan on measuring temp and pressure inside the balloon on that flight.

My filling nozzle has a groove in it.....I just tie a string around the neck at the groove location and it holds just fine...tested to 25 pounds of lift or more over the years.....I add a strip of duct tape around the bottom of the neck just to make sure. But if your fill nozzle does not have a groove in it, then duct tape alone will not be a good idea...My true favorite is as described below but I haven't used the method below for awhile since I misplaced the NWS device a few years ago during a move:

The NWS balloons also have a groove in their filling nozzle (a nicely machined aluminum affair)....they hold it on with what is essentially a wire loop (about the diameter of a coat hangar) with two ends....you squeeze on the ends and the loop gets bigger...release the wire ends and the loop contracts....it works great....wish I knew where to buy more of these...I only have one that was given me by a NWS balloon launch facility. This is the easiest and quickest way to hold a balloon to a fill nose....lots quicker and far less trouble than a hose clamp or string/duct tape. If anyone finds something like this at an auto parts store or a hardware store, let me know.

This past weekend, I launched or help launch two balloons. One (mine) I used a hose clamp like I always do. The other we used duct tape, it did a great job, I saw no indication of

it pulling away. I will admit I think the duct tape is more work, and messy, but I saw nothing that said it wasn't a viable way to do it.

I agree on the stainless Steel hose clamp. thats all we ever use. Like Mike on small flights we use 1 clamp, on heavier flights like 6 pounds of lift or more we use 2. I cringe every time I see videos of other balloon groups using duct tape anywhere on the balloon for any reason. Duct tape is yes very sticky, and will stick to almost anything. BUT it looses it's grip very fast on anything that can stretch. It acts just like those "Command" hangers from 3M. if they aren't stretched they hold tons of weight. But stretch the substrate and they loose all their grip and fall off. Quite ingenious actually. But very bad for wanting to attach anything to a balloon.

And Mikes suggestion of the sun up shadow, or a simple floodlight is a great suggestion.

The top pix is a stainless steel screw clamp like what EOSS uses. Bill's clamp is a single-piece made from piano wire - like a 1 1/4 turn loop with the ends bent up and formed into ears so you can grip it and expand the loop so it'll slip over the neck and move it directly over the groove in the fill nozzle. Release the ears and the loop closes up.

David....the spring wire hose clamp I had from the NWS is similar to this one but has much longer wire ends to allow you to open it without needed a tool.

ould go wrong today did.
1. The 35mW green lasers I was using to measure the balloon's diameter were
ot visible once the full sun started to hit the balloon.
2. A 600G balloon gets really big (see attached image). Even a slight wind
ushes it around. As the wind picked up it eventually pulled it off of the PVC
ill pipe and it slowly floated away to the west (~100 SCF of He gave it just
nough lift).
3. Oh well I at least would have some data at for the first part of the fill.
hen I got home I found out I had forgotten to enable the channel on the
ogging software. I have 46 minutes of 0.0v on 8 channels. Why would anyone
rite software that defaults to all channels off and doesn't show anything
hile it is recording?
So my experiment will have to wait until my next launch. I plan on measuring
emp and pressure inside the balloon on that flight.

hi Mike,

Exactly...the kind like are used for radiator and air intake hoses....if you can find a way to attach long (about 6 inches or more) to the ends of the wire loop clamp...then you'd have the NWS system....however the tension used for the NWS clamp is less than the auto store radiator clamps.

Hi Bill,

I've seen that type of hose clamp used on cars before, like for radiator
and air intake hoses. Might drop in and ask the guys at parts store, or
better yet, a crusty old mechanic who might point you to a make and model
car if the part store clerks are clueless.

Hi David...yes, that's similar to what my NWS clamp looks like....the NWS clamp has about 6 inch long ends though so that you don't need a special tool to use the clamp. - Bill WB8ELK

What McMaster part number, David? That link goes to a general front page for clamps (or is that what you meant to send?)

My filling nozzle has a groove in it.....I just tie a string around the neck at the groove location and it holds just fine...tested to 25 pounds of lift or more over the years.....I add a strip of duct tape around the bottom of the neck just to make sure. But if your fill nozzle does not have a groove in it, then duct tape alone will not be a good idea...My true favorite is as described below but I haven't used the method below for awhile since I misplaced the NWS device a few years ago during a move:

The NWS balloons also have a groove in their filling nozzle (a nicely machined aluminum affair)....they hold it on with what is essentially a wire loop (about the diameter of a coat hangar) with two ends....you squeeze on the ends and the loop gets bigger...release the wire ends and the loop contracts....it works great....wish I knew where to buy more of these...I only have one that was given me by a NWS balloon launch facility. This is the easiest and quickest way to hold a balloon to a fill nose....lots quicker and far less trouble than a hose clamp or string/duct tape. If anyone finds something like this at an auto parts store or a hardware store, let me know.

From: Mike Manes
Topic: 8558 Message: 8594

On 1200's EOSS uses a clove hitch around the top of the neck to seal it off long enough to remove the fill tube, and then we fold the neck over and tie it off one more time. A wrap of duct tape finishes it. Used to use a TyRap to secure the folded neck, but the new balloonmeisters don't like 'em. Never had one fail, IFAIK.

The neck on a 3000 is too thick and stiff to fold over, so that's where we use a PVC adaptor with a 0.6W x 0.05"D annular groove inside the neck with a SS hose clamp on the outside over the neck. Same idea as Pete's. Works well.

If you can't find one with the "ears" at a parts store, or maybe an
"automotive reclamation center" (aka junk yard), then you might be able
to make one using .063 or so piano wire from a hobby shop. Use a round
mandrel quite a bit smaller than the relaxed diameter desired.

Hi Joe.

Draganfly.com in Saskatoon makes a similar unit. They demonstrated it for us is at our club meeting last fall. These are amazing pieces of equipment. A local ham pilots it for the city police. Talk about a dream job!

Check this out,

First I feel still funny posting stuff like this that has absolutely nothing to do with GPSL here on the GPSL list. How is the groups transitions coming along?

Anyway check this out It can carry a 500 Gram camera aloft. It's neat but when you get to the bottom and see the pricetag, LIKE WHAT!?

8598. BASE 52 on 30 September - launch location change

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-29 17:18:53 UTC
From: BASE
Topic: 8598 Message: 8598

Dear friends,

BASE 52 is still scheduled for launch tomorrow, 30 September. I am still hoping for the same time of release, 1700 UTC (1 pm local time(Eastern Daylight Time)). We will have issues with the winds, 15 miles/hour steady with gusts to 25 miles/hour. There is quite a scatter in the flight predictions for the hours preceeding and following the scheduled launch time. A dry cold front passage at midday tomorrow makes for an uncertain landing site.

As a result, we are headed away from the forests of south central Indiana. We will launch from the Northmont School Corporation property in Montgomery County, Indiana. Approximate launch coordinates are 40.12 North and 86.91 West.

Hoping to land in a harvested field (beans or corn it doesn't matter if they're gone)!

Thanks for your support,
Howard, KC9QBN
BASE-DePauw

8599. Garmin Rino

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-23 09:16:23 UTC
From: Nicholas
Topic: 6119 Message: 8599

Mike,

To my knowledge, I am the only person flying the Garmin Rino as part of a balloon packages. I have 3 different Rino 110's that have seen flight duty.

I have one that is integrated into my APRS package. It serves double duty, since it is the gps engine (via NEMA output) for the APRS and also sends out it's Rino data via FRS.

I am very disappointed, that at the last minute I had to travel to Boston for a job over this weekend.

I fly the Rino on all my flights, I have made several GPSL's.

Cheers - Nick K0NMS

<< Is anyone launching going to use a Garmin Rino. I also saw a prediction for the landing site for those balloons and I do not seem to find it now. Where did it go or is my old age really getting to me? Thanks Mike KDØFW

Nick,

The Garmin Rino looks interesting. Does it just send the data digitally to the other radios? I actually use an FRS radio that speaks the position every 2 minutes as a backup radio. It is actually pretty fun to have a voice that everyone can plot with very little equipment.

Jerry

8601. First Potentially Habitable Exoplanet

Yahoo group: GPSL (2009 — 2010)
Date: 2010-09-30 13:41:54 UTC
From: L. Paul Verhage
Topic: 8601 Message: 8601

The number of exoplanets keeps growning. Around a red dwarf star 20 light years away, a sixth exoplanet was discovered and it resides smack dab in the habitable zone of this star. Since the planet only has a mass of 3-4 times earth's, it's rocky and warm enough to support liquid water.

http://www.newscientist.com/article/dn19519-found-first-rocky-exoplanet-that-could-host-life.html

Where's that super-space telescope when you need it?

Better yet, when can we ride the Venture Star?

Very nice. You've got to be proud of your son. He seems to do a lot of cool stuff!

That landing did look close. But that makes for an easy recovery. We don't worry too much about that here in Iowa. But we can't get pix of the Pacific, either.

It seems the pix are a bit underexposed. I find it's really difficult to get good exposures throughout a flight. Underexposure is, or so I'm told, better than over-exposure. The details are still there - your just gotta coax them out with software.

Very nice! thanks for posting the link.

Yes congrats.

You know, I suppose you could get a picture of the Pacific from Iowa if you can get the balloon high enough. My calculation shows you just ned to get the balloon to an altitude of 2.7 million feet. Ummm, how much helium wil that take?

Usually I see problems with picture exposure when the camera's light detector is covered. But that results in over exposed pictures. I wonder can result in underexposed?

8609. 3,000 F Caps

Yahoo group: GPSL (2009 — 2010)
Date: 2010-10-01 17:30:03 UTC
From: L. Paul Verhage
Topic: 8609 Message: 8609

Does anyone need a 3,000 F, 2.7 volt, 3 KW capacitor? Man, you could run your near spacecraft off of one of these charged caps.

Here's the link.
http://www.goldmine-elec.com/mailchimp/20100930/?utm_source=Electronic+Goldmine+Newsletter&utm_campaign=bb9a1752fe-September30&utm_medium=email

The caps are used electric cars.

The are 3 WH. At 2.7 volts, that's just over an amp of current for an hour. I'm thinking my near space craft needs less than 0.5 amps of current. I would need two of these in parallel for 5.4 volts which is barely enough for the LDO voltage regulator I use. However, at 0.9 pounds each, I'm still better off with batteries.

Yes I am very proud of Brenden.

Photography is my hobby so I helped with the camera setup. I told Brenden what the camera should do and he figured how to do with CHDK. I have seen a bunch of photos that were blurred from payload spin. I had Brenden set up the camera in aperture priority (AV) mode with a shutter speed of 1/500. He also setup the camera to take RAW & JPG photos, however the RAW photos failed. He used a Canon A470 which has a very small 5.75 x 4.31 mm sensor, which with a high shutter speed and a small sensor you are bound to have them come out under exposed. I didn't think it would be a big deal because he would have RAW images that I could pull out the detail. The other problem was not being able to use a UV/Haze filter. His next flight I hope he will be flying a G11. The G11 will allow him to use filters and it has a much bigger sensor. The G12 is coming out soon so I am hunting eBay for a cheap G11.

Is the UV filter on the camera lens? On the lens shoudl be fine since the air should be dry inside the camera lens.

One thing I discovered is you don't want to put a filter on the airframe. Moisture inside will condense on the window to create fogging.

I like the title of Project Finance Department!!

From: Tim
Topic: 8604 Message: 8613

<<I like the title of Project Finance Department!!>> Thanks Paul I do too, however I like Dad much more.

I am curious to know if you were using hand warmers when the fogging occurred? On one of Brenden's attempts he used hand warmers and when we retrieved it 45minutes after lift off the gear inside was so hot you could hardly touch it. (This flight never made it passed 10k and is a long story for another thread.) My point is condensation/fogging is caused by differences in temperature inside to out. The flight from which these pictures came, his payload was not even close to air tight, so the temp on the inside was the same as the outside. On this flight he insulated the batteries from the cold and some of the electronics but the camera was left to fend for itself. Yes some were underexposed but none were fogged.

Thoughts?

What are others doing to fight condensation?

Ooh, 2.7 million feet is a bit out of my league. Too much latex required.
(That's tongue-in-cheek, folks).

Interestingly, we did get a photo showing a sliver of Lake Michigan from
over NE
Iowa<http://s33.photobucket.com/albums/d94/bigheadpete/NIXHAB-4/?action=view¤t=-4LabeledPhoto.jpg>this
past winter.

Enough of that - this thread is Brenden's. A very nice job by a promising
young man.

The fogging of the lens occurs when the equipment temperature is below the dew point of the ambient air - at least in our experience. It has occurred for us only on descent after the payload box takes a good cold soak at altitude and then returns relatively quickly in to the humid air nearer the ground.

We haven't experience it but I suppose you could also get fogging on ascent passing through moisture and a change in temp.

Those of us that fly east of a longitudinal line from about El Paso, TX live with this humidity every Summer. Yuck! (Or so I've read that El Paso line is a rough dividing line between arid air and the stuff we swim through in the Summer).

From: wb8elk@aol.com
Topic: 8609 Message: 8616

Paul....you also have to look at the voltage discharge curve on these.....depending on your usable cutoff voltage, you won't get the whole capacity on Supercaps....perhaps 30 to 50 percent of the capacity depending on your voltage overhead to start and your minimum usable voltage.

- Bill WB8ELK

Subject: [GPSL] 3,000 F Caps

Does anyone need a 3,000 F, 2.7 volt, 3 KW capacitor? Man, you could run your near spacecraft off of one of these charged caps.

Here's the link.
http://www.goldmine-elec.com/mailchimp/20100930/?utm_source=Electronic+Goldmine+Newsletter&utm_campaign=bb9a1752fe-September30&utm_medium=email

The caps are used electric cars.

The are 3 WH. At 2.7 volts, that's just over an amp of current for an hour. I'm thinking my near space craft needs less than 0.5 amps of current. I would need two of these in parallel for 5.4 volts which is barely enough for the LDO voltage regulator I use. However, at 0.9 pounds each, I'm still better off with batteries.

8617. BASE 52 completed

Yahoo group: GPSL (2009 — 2010)
Date: 2010-10-01 19:59:08 UTC
From: BASE
Topic: 8617 Message: 8617

Dear friends,

BASE 52 was successfully completed yesterday. Moving the launch site and the strong and gusty (20 mph ranging to 28 mph) winds made for an exciting fill of the balloon. The 6.5 pound dead weight was lifted at approximately the half-fill point. I used the tank gauge to estimate the volume of gas in the balloon. Finally, I followed the Manes' principle and "gave it a little more gas." End result was a flight path with an ascent rate of 1200 feet/minute. Burst occurred at 90,400 feet. Total flight time of two hours.

The system returned very slowly to the ground with just the neck of the balloon and landed on the northern edge of Jamestown, Indiana in a mowed side yard between two houses.

Bill, WB8ELK, copied the DominoEX again in Alabama.

Details of the flight will be posted at www.depauw.edu/acad/physics/base

After three flights in less than three weeks, we'll take a break from flying until October 14.

Thanks for your support,
Howard, KC9QBN

The only time I've run into condensation problems is during descent thru a thick cloud layer - the payload guts are cold, and the ambient wet air is infiltrating during descent. One trick that seemed to work a bit was to install a breather port packed with silica gel desiccant. The port was made from a pill bottle with the top and bottom perforated with 0.063" drilled holes.

At a 500 mA load, a 3000 F cap will discharge 0.6V per hour, if I didn't screw up the math. At a constant current, the cap voltage will decay linearly all the way to zip. Rate of change of cap voltage:
dV/dt (V/s) = I(A)/C(F).

Congrats, Howard,

And I can't take credit for the EOSS Motto, "A little more gas". That's better attributed to our Beloved Founder and Balloonmeister Emeritus, Jack AA0P and Merle K0YUK, ca. 1990-1.

If you can't sked to avoid nasty launch winds, then compensating for false lift is a black art (aka SWAG). Sounds like you nailed it!

> Dear friends,
>
> BASE 52 was successfully completed yesterday. Moving the launch site and the strong and gusty (20 mph ranging to 28 mph) winds made for an exciting fill of the balloon. The 6.5 pound dead weight was lifted at approximately the half-fill point. I used the tank gauge to estimate the volume of gas in the balloon. Finally, I followed the Manes' principle and "gave it a little more gas." End result was a flight path with an ascent rate of 1200 feet/minute. Burst occurred at 90,400 feet. Total flight time of two hours.

Jerry

Yes, it send a digital data burst that is a Garmin format. The other Rino's if on the correct freq and tone can decode the data burst. It shows elevation and long & lat. This information is displayed on the Rino's map. Depending on which Rino you are using, you can have very detailed maps.

Nick
>

From: L. Paul Verhage
Topic: 8604 Message: 8622

My first flight encountered fogging on ascent. It appears the window on the outside of the airframe got colder than the Styrofoam walls of the airframe. This was a launch from Kansas where we do have a "small" amount of humidity. Since that first flight, I've left left the camera port open to the air and have not suffered fogging for a camera inside the airframe looking out.

I too have suffered fogging on descent (actually my camera did, I wasn't onboard ;)). It seems to be a problem for the camera outside the airframe.

I wonder if you can use a small CPU fan to blow air across the camera on descent?

Man, there's so much to learn.

Thanks, I know I can count on this group to educate.

Yep, I get a 0.6 volt drop per hour.

I've heard some super caps use aerogel (for their insulation between layers?). I had an opportunity to see aerogel at the National Air and Space Musum. The stuff looks blue cigarette smoke, but frozen in place.

From: Mike Manes
Topic: 8604 Message: 8624

Using a window over the camera view port is a mixed bag. Yes, it can fog up, but it also keeps dust out of the camera. One of the Canon 560's nastier failure modes is getting dirt in the lens extension mechanism. Eastern CO is typical of the dust bowl of the '30's in the summer.

I use a very thin film window (ink jet transparency stock with the rough side cleaned up with isopropyl rubbing alcohol). The thin stock may allow internal heat generated by the camera to keep the window fog-free if it's very close to the lens.

I've not had a great deal of luck using RainX to prevent fogging on this material, however.

From: Mike Manes
Topic: 8609 Message: 8625

Supercaps are technically known as double-layer caps from the fact that the two plates are essentially identical but separated by a very thin (nanometers thick) non-conductive (dielectric?) layer. See:

http://en.wikipedia.org/wiki/Electric_double-layer_capacitor

This thin separator is responsible for the low breakdown voltage, typically less than 5V.

Thanks for the info on the Rino 110. I have two of them and have not used them for some time. I think that the last time I used them was for your flight. I have it set to Channel 7 and code Zero. It is to bad that you missed the launch and the chase and recovery of two of the balloon payloads. The third is MIA and may get located on Saturday. What is the max altitude for the Rino 110? Mike

Man, there's so much to learn.

Thanks, I know I can count on this group to educate.

Yep, I get a 0.6 volt drop per hour.

I've heard some super caps use aerogel (for their insulation between layers?). I had an opportunity to see aerogel at the National Air and Space Musum. The stuff looks blue cigarette smoke, but frozen in place.

Paul

From: Brenden Geary
Topic: 8630 Message: 8630

What will happen to a neutrally buoyant balloon. Does it orbit with the earth looking in the same place, or does it not orbit with the earth and looking over different areas.

Brenden Geary

8631. Re: [GPSL] What happens to a neutrally buoyant balloon

Hi Brendon,

It will hang in the local air mass and therefore will move with it, same way
any other balloon does.

If your balloon is able to last for several days it will stay in the same general area as launch. Thanks for the quick reply.

No, Brendan. I said it will stay with the air mass, and the air mass
typically moves over the Earth's surface - it's called "wind".

8634. Balloon Location Challenge

Yahoo group: GPSL (2009 — 2010)
Date: 2010-10-03 00:39:16 UTC
From: Keith Kaiser
Topic: 8634 Message: 8634

Today Deb and I went out to look for the week-lost W0B-11 balloon we launched from the BSA Centennial Campout last weekend. We didn't find it. It's here;

http://aprs.fi/?call=w0b-11&mt=roadmap&z=11&timerange=5000

Above is the last position report from the balloon according to aprs.fi, it's also exactly where we started our search today. I used its last position, speed, altitude, direction, etc. to predict a landing spot, it wasn't there either.

I'd like input from any of you who care to help, to give me a new projected touchdown location. Deb and I did a two hour grid sweep of the location and didn't find the balloon. I'm not asking you to go out and find it (unless you want to), what I'm asking for is an alternate touchdown location. Our grid sweep went North an additional 500 feet, then worked East much more than that. The wind that day was very mild at this location and out of the West. This is a very large soy-bean field, the plants mostly brown are about 3 feet high.

Good luck and thanks for any help you care to provide.

No, that's only true in some cases. What mike said means that the balloon will go wherever the wind goes, at the speed of the wind. For example, we're going to be flying some neutrally buoyant balloons for 3 straight days that should travel for thousands of miles from the launch site. They will travel so far only because we will wait for the fastest wind forecast do decide when to launch. The winds you look at are the ones at your desired float altitude. We could also choose to not go far by waiting for the winds to be very slow, or look for a different altitude that has different wind speed and direction.

Simply, it's all about the wind - your balloon goes where the wind blows it to.

Thanks,
Dan

Yikes! While there are far more qualified folks than I at doing the math for a grid to locate it I'm surprised it's not there. Last position report from 1600 (what's the AGL height?) it shouldn't be too far away.

I have a lot of experience finding downed rockets at from that relatively low height and low ground speed I can't believe it too far from that point. I have learned that quite often every bit of a payload, parachute and harnesses will get sucked all the way to the ground with nothing draped up and over crops and visible from very far away..

Was there any evidence of others being in the field who may have picked it up?

Good luck!

There is a USB remote scrip that detects when you send +5V to the USB port.
It's discused in my N&V articles. What you're saying is simple to
implement.

8640. Re: [GPSL] What happens to a neutrally buoyant balloon

Yahoo group: GPSL (2009 — 2010)
Date: 2010-10-03 05:43:27 UTC
From: wb8elk@aol.com
Topic: 8630 Message: 8640

Brenden,

Depending on the winds speeds and direction at the altitude where you balloon hit neutral buoyancy (we call that a "float" condition)....it could potentially be traveling as fast as 200 mph if it's in the jet stream during the winter....or hardly moving at all during the Summer....there are different winds at different altitudes.

For example, I had several balloons parked at 100,000 feet or so for 22 hours that went from Alabama all the way to Nova Scotia Canada....that was in December....I did a flight in April that stayed over Tennessee all night long at 100,000 feet sinced at that time of year there were no winds to speak of at that altitude.,

Hope that helps,

- Bill Brown WB8ELK

No, Brendan. I said it will stay with the air mass, and the air mass
typically moves over the Earth's surface - it's called "wind".

8641. [GPSL] Aerogel meteor capture balloon

Yahoo group: GPSL (2009 — 2010)
Date: 2010-10-03 05:49:41 UTC
From: wb8elk@aol.com
Topic: 8609 Message: 8641

Dan....yes, there is one impact crater in the Aerogel that came from a Leonid (perhaps more) while the balloon was in the stratosphere.

I can't find the web page that described the results of the analysis on the Aerogel...but here's a link about the balloon flight itself...I helped with several of these from 1998 to 2001.

Man, there's so much to learn.

Thanks, I know I can count on this group to educate.

Yep, I get a 0.6 volt drop per hour.

I've heard some super caps use aerogel (for their insulation between layers?). I had an opportunity to see aerogel at the National Air and Space Musum. The stuff looks blue cigarette smoke, but frozen in place.

Keith,

I landed in a soy bean field this Summer....waist high....I had to be within 5 feet of the payload (same for the parachute and balloon) to see them...the only way I found it was by tripping over the string which was also almost impossible to see.

The parachute and balloon were wadded up in a ball and on the ground covered over by dense soybeans....I had to follow the string to even find the chute. The payload also was in the dirt and also covered over by the leaves.

I was standing at the last coordinates for the landing site....and nothing....turned out to be 50 feet away and totally invisible...that third decimal digit on the GPS reading (which is not reported on APRS) is plus or minus that amount.and can make all the difference in a soybean field.

They will be harvesting that field VERY soon....you might want to contact the farmer to keep an eye out for it....I'm sure he wouldn't want to run it through his combine without some warning.

Keith,

The W0B-11 balloon was descending at about 778 ft/min....based on ground elevation and the 1698 feet altitude of the last position report that would mean it had 1.3 minutes left to land. The tricky part is exactly how strong the winds were on the surface....it was heading due north as a general trend....even your launch was traveling due north immediately after liftoff... W0A-11 was heading due north as well just before landing....i'd check the actual landing site for W0A-11 compared with the last reading...(I don't have the actual landing site for W0A-11 or W0S...that would help determine what it did during that last 1.3 minutes)...it probably followed the same sort of path that W0A-11 did....W0S did a hook to the southwest...but that was 2 hours later and probably not a good estimate. So my recommendation is to look at where W0A-11 landed in relationship to it's last report and use that as an estimate for W0B-11 from it's last report. If you can send me the actual W0A-11 landing location as well as the W0S landing position I might be able to refined it more for you.

You know, my understanding is that some of the dust that washes off your roof and down the rain gutter is meteoritic dust. The problem is that you can't tell which is extraterrestrial and which is terrestrial without a serious microscope.

At least if you capture it in the stratosphere, it's extraterrestrial unless there has been a serious volcanic eruption or meteor impact.

It's a nice thing to do in Antartica, the balloon drifts around the South Pole in about a week's time.

Almost as if you were orbiting the pole.

Mike the Rino works above 100K in the NEMA output so it will still provide the GPS data to the APRS stystem.

But because of internal coding it is limited to just over 98K while sending information to other Rino's using the FRS freq. Once it is below 98K it again shows the correct altitude.

Nick (or anyone else for that matter),
Do you have any info about the over the air protocol used in these radios. I am interested in decoding for display on a PC based map.

Thanks. /s/SM2. K0SCC

First of all I would like to thank everybody who answered my question. I am doing a science fair project and have a few questions. First here is what I am doing. I want to launch a repeater to near space that you can use during a natural disaster or other emergency. I have two ideas on how I can do it.

Version 1.0
Have a payload with a lightweight repeater, tracking and a gps. Along with a parachute, balloon, and antenna. The balloon will only will only have 1 pound of extra lift, so there will be a slow accent to 100,000. Then a large parachute for a slow decent. The reason for a slow accent and decent is for a long flight time is to maximize the amount of time the repeater is in the air. Even with that it will only be in the air for 2 - 5 hours. This could give the needed time to setup a more permeant solution or there could be more then one balloon that could launched and recovered and launched again as a longer solution.

Version 2.0
Have a payload with a lightweight repeater, tracker, and a gps. Along with a parachute, balloon, antenna, flasher light, and radar reflector. The balloon will be inflated for it to float around a the altitudes of 250ft(tethered) to 60,000ft(neutrally buoyant) The altitude would be chosen by the size of "red zone" and wind conditions. I will have to see what FAA restrictions we would have to follow for a payload to be floating around in commercial air space for an extended amount of time. My guess is that it will be able to have one of these up for a day or two.

What do you think?

Brenden

hi Brenden,

The repeater is a good science fair project....I just demonstrated that here for a National Geographic TV show that will come out in January but used what is called a Simplex Repeater (I used the Argent Data Simplex Repeater module connected to a handie-talkie). It takes getting used to the fact that it records for 20 seconds (depending on how you set it up) and then replays what it hears). The good news is that it makes for a simple repeater relay for emergency communications with just one radio instead of the two you'd need for a crossband repeater relay. I used the Alinco DJ-C7 radio for my last flight. We had folks in Kentucky and Ohio talking to us here in Alabama....we are 400 miles from Ohio and I was just using a handie-talkie on the ground to talk through the balloon repeater.

You can also do a crossband repeater, but you will have to wire up a circuit board to adjust the volume levels properly and worry about desense to the receiver since the transmitter is nearby.....I would recommend the simplex repeater option for your system.

I'd recommend a standard up and down flight if you want to get your repeater payload back....we're getting into a time of year when winds are increasing and you could go 150 to 200 miles downrange or more with an extended flight....better to keep it closer by going with 1000 feet/min ascent rate....you'll still get up to 2 hours of communications time for your demonstration. But you can certainly highlight the possibility of extended flight for your science fair display...that would be a good topic. Achieving a float conidition at a specific altitude is not at all easy to do...you have to get things just right to pull it off.

The easiest way to do an extended flight is to just simply put a small amount of positive lift in the balloon....going up at 500 ft/min will double your flight time....a bigger parachute will help for the descent time extension as well....but keep in mind my comment above about getting your payload back if you do this....also measuring just a few ounces of positive lift will be difficult to achieve unless you inflate in a barn or hangar building....better to have plenty of lift to ensure a successful flight.

Use the Ascent rate calculator at: www.nearspaceventures.com to determine the amount of lift you need to achieve 1000 feet/min for the weight of your parachute and payloads......you can also use the Flight prediction software on that website to calculate where your balloon will travel as well. I wrote these original programs to do this in 1987 and we've been refining it since then and it now is pretty accurate. Thanks to the folks at NearspaceVentures they have converted it for use on an interactive webpage.

To determine the amount of helium you'll need...download the Liftwin program that you'll find in the software downloads at: www.eoss.org
You can also download the full Balloon Track prediction program that uses the same algorithms as the web-based Balloon Track at NearSpace Ventures.

I advised a local 8th grade student here last year ... she did her Science Fair project on High altitude balloon photography and won the state competition in Alabama.

Feel free to contact me directly if you have any questions....where are you located by the way?

Robert,

I tested out flying a 915 MHz 100 milliwatt Zigbee PRO XSC module this Summer....they are inexpensive and capable of mesh networking.....I used a stock rubber duck antenna and a simple 8 dBi patch antenna on the ground with about 50 percent copy at 20 miles distance (20 miles straight above my house in fact). The balloon didn't get any farther away than that during this particular mission....high gain ground antenna combined with a better antenna on the balloon may allow some decent range out to 50 miles or more with these....I plan to do another round of experiments with these soon....you can also use them for inter-payload comms on the flight train.

The alternative is to fly the Digi 9XTend units but they are almost $200 each...but do put out a watt....so you'd get very decent range with these....I've had good copy on these out to well over 100 miles...once again high gain antenna on the ground (Az/El rotor mount) is a big plus.

One Additional note Brenden,

These balloons HATE to be tethered. Any wind at all and it won't be
very high off the ground.

You may have it on 250 feet of line and when it's dead calm it may be at
250 feet. But if there is much wind at all 10 Mph? it will blow it
over and be almost on the ground actually.

From: Keith Kaiser
Topic: 8634 Message: 8654

This helps me a lot to confirm that my projected touchdown was at least close. I had figured 38d 52.74, -93d 37.52 so you can see we are only 61.9 feet apart on our projections.

But that also confirms that despite Deb and I doing what I felt was a very good job of looking for it, we didn't look hard enough. It's there we just have to find it.

Thank you Bill and others for taking the time to look into this mystery. We're already planning on another trip this Saturday to try again to find it. Anyone interested is welcome to join in.

>> Keith,
>>
>> The W0B-11 balloon was descending at about 778 ft/min....based on ground elevation and the 1698 feet altitude of the last position report that would mean it had 1.3 minutes left to land. The tricky part is exactly how strong the winds were on the surface....it was heading due north as a general trend....even your launch was traveling due north immediately after liftoff... W0A-11 was heading due north as well just before landing....i'd check the actual landing site for W0A-11 compared with the last reading...(I don't have the actual landing site for W0A-11 or W0S...that would help determine what it did during that last 1.3 minutes)...it probably followed the same sort of path that W0A-11 did....W0S did a hook to the southwest...but that was 2 hours later and probably not a good estimate. So my recommendation is to look at where W0A-11 landed in relationship to it's last report and use that as an estimate for W0B-11 from it's last report. If you can send me the actual W0A-11 landing location as well as the W0S landing position I might be able to refined it more for you.

8655. A little more detail on White Star Balloon flights for the curious

Yahoo group: GPSL (2009 — 2010)
Date: 2010-10-04 15:17:29 UTC
From: Dan Bowen
Topic: 8655 Message: 8655

Hi All,

One question first: can someone find a reference for the rule on HF data telemetry on 10.146MHz from balloons over the US? We didn't do it on SNOX cause we thought it wasn't legal, but now can't find a reference to the regs that say so...

The White Star program is starting from the open-sourced Spirit of Knoxville Transatlantic Balloon system designs and research information and building upon them. (SNOX data/research available at http://web.me.com/dbowen1/Spirit_of_Knoxville_Published_Information/SNOX_DOCS_Blog/SNOX_DOCS_Blog.html and http://wiki.whitestarballoon.com/doku.php?id=analysis:snox) There are two member of the old SNOX team participating in White Star, Carl Lyster, WA4ADG, who designed and built all the electronics on SNOX, and myself. Bill Brown, WB8ELK, may also be contributing and flying hardware onboard as well.

We're taking a completely open stance on info sharing right from the start. We'd like to welcome others to compete, poke around our code, spectate, comment, compete or collaborate. All* of our technical details are/will be available at http://wiki.whitestarballoon.com.

Anyone in the balloon community is welcome to listen in on our meetings/work sessions, we will have a speakerphone at all the meetings tied into the conference call number. We have meetings VERY often in this rush to the Jet Stream season, usually 3-5 times per week, plus one scheduled conference call per week. Events calendar: http://www.google.com/calendar/embed?src=d2hpdGVzdGFyYmFsbG9vbkBnbWFpbC5jb20

There are multiple small teams working in parallel on the many mini-projects that are required to do a long duration balloon. We hope that the stuff we put together can be used by others as a starting point to spend time solving the next problems, getting better, going farther, easier. You will find info on the wiki on mini-projects that also still need help, which you're welcome to contribute to.

For the first flight or two we'll be collecting a large amount of scientific data, at a very high data rate. We're aiming to have 1 minute data logging for the duration of the mission, and have all of it relayed down via telemetry, not stored in a data logger. (telemetry may be in bursts though, not every minute) For the first flight the Global Western TA Zero Pressure balloon envelopes will be instrumented to gather data on exactly what happens to a small ZP balloon. Temperature will be measured at three heights in the balloon, and differential air pressure (vs outside) will be measured at the top and bottom of the balloon. The temperature from solar heating is quite important to being able to understand and predict balloon performance, and very little data exists for that on this size of balloon.

There will be a mems barometric altimeter onboard the payload for altitude holding, instead of GPS altitude. The Telemetry is likely going to be a hybrid satellite data/HF system, where satellite uplink commands are used to pause the HF telemetry when no propagation is available. satellite is cheap if you only send about 3KB per month, but gets expensive quick as your data xferred goes up. Telemetry format and data modes are being explored now.

Data compression will be used for telemetry data, in a defined method so data can be independently verified if desired. We're looking at ASCII 110 baud, 8 data bits, 1 stop bit, as an easy-to implement method, but also are looking at DominoEX. The problem with DominoEX is that it doesn't appear to allow 8-bit bytes. We'd really like a method that supports 8-bit data bytes to ease the flight computer programming. We'd welcome any suggestions here.

Telemetry is going to be sent at regular intervals over HF during normal propagation. Position-only data will be sent via satellite at all times to ensure ATC knows where we are at all times. After propagation dropouts, however, all the backlogged data will be sent in a CONTINUOUS BURST until caught up with realtime. This will be commanded via satellite uplink.

There will likely be a tip-over cutdown, remotely commandable via satellite.

Ballast will be liquid alcohol, using an identical system to SNOX for the first SpeedBall or two, as we develop improvements to shed more than just 6lbs.

We'll be communicating with every ATC center we pass through via telephone for all phases of the flight. This will be an intensive job, requiring a phone call at least once every 30 minutes, for 24-72 hours while over the ocean. We would like some help on this if anyone is interested, so we can do this in shifts. Training would be provided, but pilots or ATC controllers are preferable.

Background on the names
SpeedBall will be the name of all our Jet Stream flights - a nod to the other trans-atlantic speeder, the Concorde. It's ATC radio callsign was SpeedBird. The HighBall-1 latex flight this weekend is merely to get our launch crew some launch coordination experience, and our local ATC some comfort with us. It's not going to go fast, so no SpeedBall name for it. I know HighBall isn't very original, but it's a pretty typical latex flight anyway!

Thanks,
Dan

*There is a private section of the wiki, but I'll tell you what's in there - service plan data that we had to sign an NDA to get from Orbcomm, passwords to websites like twitter, our personal members contact info, and our money records.

Hi Keith,

An independent DF beacon sure would help you narrow down your search. Don't leave the launch site without it! :=)

Dan;

I just happen to have seen what I think you're looking for in the ARRL Extra Class License Manual - 2008 version.

First of all per this manual and the test, a balloon should be considered an earth station since its below 50 km in altitude. See page 3-13, table 3-6 which references part 97 section 97.3(a):
"(16) Earth Station. An amateur station located on or within 50 km of the earth's surface intended for communications with space stations or other earth stations by means of one or more other objects in space.

(40) Space Station. An amateur station located more than 50 km above the earth's surface."

Since it says an object, to me that would include bouncing a signal off of the e-layer or f-layer :)

Than on page 3-4 it says: "The 30 meter band is allocated to amateurs on a secondary basis at the World Administrative Radio Conference in 1977. Amateurs may only transmit CW and data signals on this band and are limited to 200 W output power... ". On page 3-5, the book says that should the balloon travel into airspace controlled by another country, then will need an appropriate license to operate on 30 m.

Finally the book reminds us to seek permission of the owner of the aircraft before installing a radio or transmitting, I'm sure you have that.

So while I'm not a lawyer, my reading of the book would say that its legal to send telemetry on 10.146 MHz while over the US or international waters.

Don

Dan....the automated data portion of the 30m band goes from 10.140 to 10.150 MHz over the US....but it is a bit crowded with packet gateways on the upper end of that....I chose 10.142 as a good compromise but you will get a few PSK31 stations there but seemed to be the quietest portion for my flights I did on 30m.

- Bill

Temperature will be measured at three heights in the balloon, and differential air pressure (vs outside) w ill be measured at the top and bottom of the balloon. The temperature from solar heating is quite important to being able to understand and predict balloon performance, and very little data exists for that on this size of balloon.

There will be a mems barometric altimeter onboard the payload for altitude holding, instead of GPS altitude. The Telemetry is likely going to be a hybrid satellite data/HF system, where satellite uplink commands are used to pause the HF telemetry when no propagation is available. satellite is cheap if you only send about 3KB per month, but gets expensive quick as your data xferred goes up. Telemetry format and data modes are being explored now. Data compression will be used for telemetry data, in a defined method so data can be independently verified if desired. We're looking at ASCII 110 baud, 8 data bits, 1 stop bit, as an easy-to implement method, but also are looking at DominoEX. The problem with DominoEX is that it doesn't appear to all ow 8-bit bytes. We'd really like a method that supports 8-bit data bytes to ease the flight computer programming. We'd welcome any suggestions here.

Telemetry is going to be sent at regular intervals over HF during normal propagation. Position-only data will be sent via satellite at all times to ensure ATC knows where we are at all times. After propagation dropouts, however, all the backlogged data will be sent in a CONTINUOUS BURST until caught up with realtime. This will be commanded via satellite uplink.

There will likely be a tip-over cutdown, remotely commandable via satellite.

Ballast will be liquid alcohol, using an identical system to SNOX for the first SpeedBall or two, as we develop improvements to shed more than just 6lbs.

We'll be communicating with every ATC center we pass through via telephone for all phases of the flight. This will be an intensive job, requiring a phone call at least once every 30 minutes, for 24-72 hours while over the ocean. We would like some help on this if anyone is interested, so we can do this in shifts. Training would be provided, but pilots or ATC controllers are preferable.

Background on the names
SpeedBall will be the name of all our Jet Stream flights - a nod to the other trans-atlantic speeder, the Concorde. It's ATC radio callsign was SpeedBird. The HighBall-1 latex flight this weekend is merely to get our launch crew some launch coordination experience, and our local ATC some comfort with us. It's not going to go fast, so no SpeedBall name for it. I know HighBall isn't very original, but it's a pretty typical latex flight anyway!

Thanks,
Dan

*There is a private section of the wiki, but I'll tell you what's in there - service plan data that we had to sign an NDA to get from Orbcomm, passwords to websites like twitter, our personal members contact info, and our money records.

More precisely, 98396 ft is the over-the-air limit of the Rino protocol, but like Nick says the GPS works fine above that and still provides the correct altitude on the serial port.

Note that there was a bug in some of the early units that wouldn't decode the altitude properly (it got clipped at 46739 ft.) The bug is on the receive side. If you're using a 520/530/520HCx/520HCx for receive, make sure your have the latest software. I don't think the bug was ever fixed in the 100-series. But again, this only affects the receiver so a 100-series can be used as the transmitter without problems.

The Rino 110 looks like it may be a good backup tracker to help you locate the landing site. Before purchasing one, I'd be curious to know if you can set it to send position reports on a regular basis. That way I could launch it as a backup tracker.

8663. Balloon flight climatology

Yahoo group: GPSL (2009 — 2010)
Date: 2010-10-04 20:54:25 UTC
From: Mark Conner
Topic: 8663 Message: 8663
Attachments: 1 described; binary payloads are missing from this source WARC

Attached is an animated GIF showing the landing sites of 31 years of simulated daily balloon flights. The wind data is taken from the NCDC Climate Forecast System Reanalysis archive, which has pretty high vertical resolution up to 1 mb of altitude. The plots show the launch site as a yellow plus, each landing as a red dot, and the gray squares showing the landing plot density on a 0.25-degree grid (the whiter the box the more landings in it). The green rings are 50 statute miles in diameter and are a true distance on the earth and not an approximation from a lat/lon grid.

In general it shows what one would expect, with longer average distances in the winter. No big surprises in the plots, except I had expected more long-distance landings in the winter (the longest I saw was about 250 miles). However, in the winter a strong jet stream is often correlated with light winds in the lower layers, so while it may be moving at 200 mph in the jet, it may not be in it for very long vertically.

It would also be interesting to run this for other areas of the country, which I haven't done yet. It takes a few hours to extract wind profiles for a new location out of 60 Gb of global analysis data, but once that's done simulating the 11,000+ balloon flights takes under a minute.

I did compare my flight profiles to what NSV generates on their website and while not exact we're within a few miles of the sample 125-mile flight profile I compared (direction is good, my profile gives slightly longer distances).

That's pretty cool. Do you have the data in a spreadsheet form? I'm
wondering if I could run SPSS against it to analyze the variances. Perhaps
I could even run a regression against the data.

The variance in the data appears as the spread-outedness of the plots. As
the balloon travels farther, the landing zones spread out in extent.

From: L. Paul Verhage
Topic: 8667 Message: 8667

I had a chance to watch the newly restored Metropolis (1928 Fritz Lang) last night in Lawrence with live muscial accompaniment.

The restored version puts 25 minutes back into the movie so it makes much more sense. Lang did a great job on this silent movie, so if you get a chance to watch it, I'd recommend it.

In Novermber the restored version will be available along with the musical accompaniment by the group, Alloy, that I listened to. Good selection of music for the movie.

I ran a one way anova (analysis of variance) real quick (I'm about to head to class). The blasted SPSS in the GRA office won't save output as a PDF, so I've attached a screen print of the output.

The comparison of means I ran looked at changes in lattitude and longitude based on the month (it combined all years). So in the Descriptives, it's displaying the means for each month (1 to 12) for lat and long.

N = number of records
Mean is the average lat or long
Std Deviation is how much variation there is in lat and long. A single SD encompasses 32% of the records. The smaller the SD, the tighter the clustering of the data.
Std Error is something I need to look up again
Confidence Intervals tells us how much range there is for 95% of the records.

In the ANOVA table, the sum or sqares is telling us about the amount of variation within months and between months.

In regards to lattitude, the variation within each month is far less than the variation we see between the average (mean) between the months.
The effect is far less pronounced in longitude.

So we see a lot more overlap in lattiude than we see in longitude.

I've got to drive to class, so I'll look at this some more tomorrow and run additional analysis.

--
Onwards and Upwards,
Paul

Thanks for your kind research Don! I apologize for my delay in responding, I forgot that I have all my GPSL emails drop into a separate folder from my inbox, and hadn't peeked in there since the weekend!
Dan

On Oct 04, 2010, at 12:40 PM, DON FRASER <wa9wws@...> wrote:

Dan;

I just happen to have seen what I think you're looking for in the ARRL Extra Class License Manual - 2008 version.

First of all per this manual and the test, a balloon should be considered an earth station since its below 50 km in altitude. See page 3-13, table 3-6 which references part 97 section 97.3(a):
"(16) Earth Station. An amateur station located on or within 50 km of the earth's surface intended for communications with space stations or other earth stations by means of one or more other objects in space.

(40) Space Station. An amateur station located more than 50 km above the earth's surface."

Since it says an object, to me that would include bouncing a signal off of the e-layer or f-layer :)

Than on page 3-4 it says: "The 30 meter band is allocated to amateurs on a secondary basis at the World Administrative Radio Conference in 1977. Amateurs may only transmit CW and data signals on this band and are limited to 200 W output power... ". On page 3-5, the book says that should the balloon travel into airspace controlled by another country, then will need an appropriate license to operate on 30 m.

Finally the book reminds us to seek permission of the owner of the aircraft before installing a radio or transmitting, I'm sure you have that.

So while I'm not a lawyer, my reading of the book would say that its legal to send telemetry on 10.146 MHz while over the US or international waters.

Subject: [GPSL] A little more detail on White Star Balloon flights for the curious

Hi All,

One question first: can someone find a reference for the rule on HF data telemetry on 10.146MHz from balloons over the US? We didn't do it on SNOX cause we thought it wasn't

legal, but now can't find a reference to the regs that say so...

The White Star program is starting from the open-sourced Spirit of Knoxville Transatlantic Balloon system designs and research information and building upon them. (SNOX data/research available at http://web.me.com/dbowen1/Spirit_of_Knoxville_Published_Information/SNOX_DOCS_Blog/SNOX_DOCS_Blog.html and http://wiki.whitestarballoon.com/doku.php?id=analysis:snox) There are two member of the old SNOX team participating in White Star, Carl Lyster, WA4ADG, who designed and built all the electronics on SNOX, and myself. Bill Brown, WB8ELK, may also be contributing and flying hardware onboard as well.

We're taking a completely open stance on info sharing right from the start. We'd like to welcome others to compete, poke around our code, spectate, comment, compete or collaborate. All* of our technical details are/will be available at http://wiki.whitestarballoon.com.

Anyone in the balloon community is welcome to listen in on our meetings/work sessions, we will have a speakerphone at all the meetings tied into the conference call number. We have meetings VERY often in this rush to the Jet Stream season, usually 3-5 times per week, plus one scheduled conference call per week. Events calendar: http://www.google.com/calendar/embed?src=d2hpdGVzdGFyYmFsbG9vbkBnbWFpbC5jb20

There are multiple small teams working in parallel on the many mini-projects that are required to do a long duration balloon. We hope that the stuff we put together can be used by others as a starting point to spend time solving the next problems, getting better, going farther, easier. You will find info on the wiki on mini-projects that also still need help, which you're welcome to contribute to

For the first flight or two we'll be collecting a large amount of scientific data, at a very high data rate. We're aiming to have 1 minute data logging for the duration of the mission, and have all of it relayed down via telemetry, not stored in a data logger. (telemetry may be in bursts though, not every minute) For the first flight the Global Western TA Zero Pressure balloon envelopes will be instrumented to gather data on exactly what happens to a small ZP balloon. Temperature will be measured at three heights in the balloon, and differential air pressure (vs outside) will be measured at the top and bottom of the balloon. The temperature from solar heating is quite important to being able to understand and predict balloon performance, and very little data exists for that on this size of balloon.

There will be a mems barometric altimeter onboard the payload for altitude holding, instead of GPS altitude. The Telemetry is likely going to be a hybrid satellite data/HF system, where satellite uplink commands are used to pause the HF telemetry when no propagation is available. satellite is cheap if you only send about 3KB per month, but gets expensive quick as your data xferred goes up. Telemetry format and data modes are being explored now. Data compression will be used for telemetry data, in a defined method so data can be independently verified if desired. We're looking at ASCII 110 baud, 8 data bits, 1 stop bit, as an easy-to implement method, but also are looking at DominoEX. The problem with DominoEX is that it doesn't appear to allow 8-bit bytes. We'd really like a method that supports 8-bit data bytes to ease the flight computer programming. We'd welcome any suggestions here.

Telemetry is going to be sent at regular intervals over HF during normal propagation. Position-only data will be sent via satellite at all times to ensure ATC knows where we are at all times. After propagation dropouts, however, all the backlogged data will be sent in

a CONTINUOUS BURST until caught up with realtime. This will be commanded via satellite uplink.

There will likely be a tip-over cutdown, remotely commandable via satellite.

Ballast will be liquid alcohol, using an identical system to SNOX for the first SpeedBall or two, as we develop improvements to shed more than just 6lbs.

We'll be communicating with every ATC center we pass through via telephone for all phases of the flight. This will be an intensive job, requiring a phone call at least once every 30 minutes, for 24-72 hours while over the ocean. We would like some help on this if anyone is interested, so we can do this in shifts. Training would be provided, but pilots or ATC controllers are preferable.

Background on the names
SpeedBall will be the name of all our Jet Stream flights - a nod to the other trans-atlantic speeder, the Concorde. It's ATC radio callsign was SpeedBird. The HighBall-1 latex flight this weekend is merely to get our launch crew some launch coordination experience, and our local ATC some comfort with us. It's not going to go fast, so no SpeedBall name for it. I know HighBall isn't very original, but it's a pretty typical latex flight anyway!

Thanks,
Dan

*There is a private section of the wiki, but I'll tell you what's in there - service plan data that we had to sign an NDA to get from Orbcomm, passwords to websites like twitter, our personal members contact info, and our money records.

8674. ZP Balloons for sale

Yahoo group: GPSL (2009 — 2010)
Date: 2010-10-08 18:38:19 UTC
From: dbowen1
Topic: 8674 Message: 8674

Hi All,

We're going to be buying ZP balloons from Global Western this month. There's a 10 item minimum, at $300, but we only need 5. We'll buy em all if we have to, and sell them later, but it makes it easier if we don't have to pay the whole cost of 10. Someone else has expressed interest, but not commitment, to split the order with us. So we're looking around to make sure we have backup. Anyone out there interested in buying 1 to 5 ~1000 cu ft zero pressure polyethylene balloons? Their design may change slightly, but the general idea is ~1000 cu ft, 11 to 12 lb payload, float somewhere (TBD exactly soon) between 30,000 and 40,000 ft.

Drop me a line if interested.

Thanks,

Dan Bowen

White Star Balloon team

One item of interest is that his capsule was almost directly attached to the neck of the balloon. This should improve the stability a lot. I might take a whack at a similar approach - you should get very stable ascent video, but descent won't be so good.

From our balloons motions I don't think it would be very stable, and
after watching the video from the balloon, it's agrees with me. it's
not stable at all.

A few ARBONET flights have the payload directly connected to the balloon, including ARBONET 4 which is going up tomorrow. Yes, it dramatically stabilizes the video. Most of the spinning is created by the tether lines.

This configuration makes the parachute portion difficult. In this case ARBONET is studying the balloon pressure to understand the dynamics of what happens with the pressure and how we can intelligently work with the pressure to facilitate a return to earth via the balloon and not the parachute.

Bill brown has also done some of these flights, along with his students as a project. Bill and I talked about the methods of venting and and we had very similar ideas here. Tomorrow's flight will be flying our new balloon board with integral voice beacon on 70 cm as well as log the data into internal memory.

A video camera will be facing outward this time rather than down, hoping to capture some of the views of earth and the horizon.

See ARBONET.NET for more info on this flight.

Well the decision of making a new group for just chit chat like now
but using Google Groups instead, was a slam dunk now. At least in my
opinion they just made it simple, but they will be shutting down the
ability to store files on the group sites.

http://groups-announcements.blogspot.com/2010/09/notice-about-pages-and-files.html?hl=en

Without that handy feature it will kinda suck.

I think the New York guys would have had better luck with a few improved ingredients:

1) Reduced ascent rate

2) Weight below the camera platform in the way of other payloads, or a drag chute like we had. This provide a "tail" of sorts, just like when we added a tail to our kites as kids. Our drag chute was actually an accident, but sure worked well to keep the balloon stable and the ascent in check!

From: Jerry Gable
Topic: 8675 Message: 8683

Michael,

Let us know how the pressure measurement goes. I plan on launching one in a couple of weeks to measure the pressure also. The more data points we can get the better.

Jerry

A few ARBONET flights have the payload directly connected to the balloon, including ARBONET 4 which is going up tomorrow. Yes, it dramatically stabilizes the video. Most of the spinning is created by the tether lines.

This configuration makes the parachute portion difficult. In this case ARBONET is studying the balloon pressure to understand the dynamics of what happens with the pressure and how we can intelligently work with the pressure to facilitate a return to earth via the balloon and not the parachute.

Bill brown has also done some of these flights, along with his students as a project. Bill and I talked about the methods of venting and and we had very similar ideas here. Tomorrow's flight will be flying our new balloon board with integral voice beacon on 70 cm as well as log the data into internal memory.

A video camera will be facing outward this time rather than down, hoping to capture some of the views of earth and the horizon.

See ARBONET.NET for more info on this flight.

And ... they're OFF!

http://www.balloonfiesta.com/GasTracking/2010/

So far, their trajectories are all generally ESE, averaging
about 20 mph. Unless there's a major wind shift, it doesn't appear
that they'll be coming over Colorado. But W TX is a pretty sure shot
this AM.

8689. America's Challenge balloons moving NE through Missouri

Yahoo group: GPSL (2009 — 2010)
Date: 2010-10-10 17:24:02 UTC
From: Mark Conner
Topic: 8689 Message: 8689

Look for the K5GAS-* callsigns on APRS. Three of the balloons are in north-central Missouri, the fourth is south of Columbia MO. All are moving NE at about 25-30 mph. They should continue NE over northern Illinois and Indiana over the next 36 hours if they continue flying.

Thanks Lynn!

I have copied this to a few other yahoo reflector groups for their interest (see Lynn's link below).

That is very interesting to see how far we hit digi's and repeaters, and it appears there was no problem with flooding the network, still at 300mw we were well heard from a few thousand feet through near 84K ft!

I set this flight at Wide2-1 because we are in the middle of nowhere at times and this APRS tracker (MicroTrak-300) could not switch to the desirable no path at a few thousand off the ground.

I appreciate you running this report, I really like seeing that data!

Announcing the next CARC (Collins Amateur Radio Club) meeting (Tues., Oct. 19 2010)iHAB presentation at 5:00 PM. This meeting is going to be held at the St. Lukes Hospital Auditorium, Cedar Rapids IA. The reason we are holding it at the auditorium this time is due to this meeting's speaker: Mr. Marshall Dias (WØOTM), the individual responsible for the two iHAB (Iowa High Altitude Balloon) launches in August and October this year. Due to the interest in Mr. Dias' project, we have decided to open this meeting to the public so that Mr. Dias can present to as big an audience as possible. Pass the word along to any who might be interested in attending. http://www.ihabproject.com/
Now if I can just remember to go.

They don't say how big it is, but it's gotta be gigantic! being
flat the volume is gonna be hard to make, then it's a rigid airship so
again it has a lot of weight, then if it's capable of lifting 165 tons
of payload. Like how huge is this thing!

I'm guessing that the envelope is neutrally buoyant. The props around the periphery are cyclic, so they can produce thrust both vertically and horizontally - like on a helo.

Mike;

Would the balloon envelope also generate lift if moving faster than the air around it?

8706. BASE 53 on Thursday

Yahoo group: GPSL (2009 — 2010)
Date: 2010-10-12 15:35:30 UTC
From: BASE
Topic: 8706 Message: 8706

BASE 53 is still scheduled for launch around 1700 UTC (1 pm Eastern Daylight Time) on Thursday, October 14.

Predicted trajectory winds will move the launch site to the Northmont Schools (north of Crawfordsville, Indiana). Predicted landing is between Columbus and Greensburg, Indiana. Target ascent rate of 1000 ft/min. 1200 gram Helium filled balloon with a payload of just under 8 pounds. Anticipated burst altitude of 95,000 feet.

Some radio changes. Multimode (DominoEX 22, Hellschrieber, CW) will be on 146.565 MHz with the call sign: N9QGS.

Primary ARPS on 144.39 MHz under W9YJ-11 at minute +52 seconds.
Secondary ARPS on 144.39 MHz under N9QGS-ll.

Flight may be postponed if strong surface winds arise on Thursday afternoon.

Thanks for your support,
Howard, KC9QBN

Hello Paul.
I just got the note from Keith wa0tjt about the balloon launch in Topeka on Saturday. I will be at the last big local hamfest in the Kansas City area this year. I would think that most hams would try to make this one also. If you launch on Sunday or next week let me know as I would be glad to chase and help recover it. Have fun be safe! Mike KDØFW

There may also be an air ballast bladder inside the envelope to control the
free lift. That would make a lot of sense, given the stated mission and the
rigid envelope.

Thanks. Is it possible you could keep an eye on the near spacecraft at the hamfest? My cell number is 785 230-6866. It would be nice to know that even if people can't go on chase, they can still help out with backup tracking.

I may get another launch from KU in a week or two.

From: Mark Conner
Topic: 8711 Message: 8711

I sent this to John Derbyshire and he posted it to The Corner (National Review's main blog) without editing about 15 minutes ago. This should attract some more interest to ARHAB. Now I wish I'd have taken more time to write it up!

I'm not sure what the hit count per day is for NR's blog, but it's gotta be six figures.

Have you done a prediction on where your balloon will travel. If it would travel about the same as the 3 balloons launched at the boy scout camp a few weeks ago it might just be coming down towards the hamfest location. If they have a wireless connection at the hamfest maybe I could keep an eye out for it. I will check and see. Mike KDØFW

8714. BASE 53 launch location change

Yahoo group: GPSL (2009 — 2010)
Date: 2010-10-14 01:39:45 UTC
From: BASE
Topic: 8714 Message: 8714

DePauw still plans to fly BASE 53 on Thursday (tomorrow), 14 October. Surface winds will be significant, over 10 mph with gusts to 18 mph, but not nearly as strong as for BASE 52.

The predictions for tomorrow's flight have stabilized. The launch location will be moved to the intersection of State Road 28 and US 52 near Clarks Hill, Indiana (40.253 N,86.697 W). Considering our departure constraints from DePauw, the launch may occur somewhat later than 1700 UTC (1 pm EDT).

Same radio configuration as announced early this week:

Primary APRS on 144.39 MHz with callsign W9YJ-11 (no path on +52 seconds). Secondary APRS on 144.39 MHz with callsign N9QGS-11.

Multimode (including DominoEX 22, CW, Hellschrieber) on 146.565 MHz with N9QGS

Landing predicted of 39.38N, 85.50W. Flight path looks very winter like, nearly straight line, 91 miles at 139 degrees, in just over two hours.

Thanks for your support,
Howard, KC9QBN

This one was a nice target of opportunity on a blog I read pretty regularly. However, it didn't result in as much of a spike in the YouTube view count as I thought it might. Even so, I encourage anyone who encounters such stories on news sites and so on to at least add a comment and/or contact the story author to provide more context.

John Derbyshire really likes this sort of thing. If you go to his website, you'll see how he documented the construction of a treehouse in his back yard. Pretty fascinating - he's got a great mind for engineering even though he makes his money as a writer. I wouldn't put it past him to try something like (AR)HAB himself and feature it at some point.

I posted this before.
I have two XT09-PKI-RDA 1 Watt/900 MHz stand-alone radio modems.
I was just wondering how to use them and to connect them with a camera that takes every 30 sec. or so images and download them to a computer with the same modem ?
I just want to know what parts are needed inbetween this setup to make it work. I hope there some technicians out there who might have a suggestion ..

8723. GPSL 2011

Yahoo group: GPSL (2009 — 2010)
Date: 2010-10-15 10:28:46 UTC
From: Rob Wright
Topic: 8723 Message: 8723

Greetings,

Edge of Space Sciences is pleased to welcome the Great Plains Super Launch community to Colorado for the 2011 conference. The Pikes Peak Community College has generously offered meeting space at their Rampart Range Campus just North of Colorado Springs. The launch date has been scheduled for July 30, 2011.

EOSS would like to gauge your interest in a 2-day conference followed by the launch. Our proposed schedule features technical sessions and workshops on Thursday and Friday. We're still forming our plans on the workshops, but they will be hands-on sessions. EOSS welcomes your thoughts on whether you would be interested in such a 3-day event. The planning committee eagerly awaits your reply no later than October 29th, 2010 please.

In addition, we are also soliciting your thoughts on extending the event one more day to include tours of the United States Air Force Academy and the U.S. Olympic Training Center. These tours would be on Wed. morning and afternoon. They would be followed by a chuck wagon dinner at the Flying W ranch on Wed. night. The tours will most likely be free, but the dinner is $22 a head and includes a western music show after dinner. It's a most popular attraction in Colorado Springs. Great for the whole family. You would not have to attend the Wed. events to attend the 2-day tech session and then the launch on Sat.

Many may also be interested in driving out to Colorado on the Saturday and Sunday before GPSL and seeing a bit more of Colorado. A nice two-day extension would include Sunday night in Estes Park right on the edge of Rocky Mountain National Park. There's much too do in both the RMNP and in Estes Park, perhaps including a drive up Trail Edge Road (it's paved) to 12, 183 ft. Tuesday would be drive into the mountains via I-70 and then a trip over Loveland Pass and then down into the ski towns of Keystone and Breckenridge. Then on over Hoosier Pass and into Fairplay and across South Park to meet U.S. Rt 24 and on into Colorado Springs. The sharp-eyed will be able to see seven of Colorado's 54 14,000 ft. peaks on this drive. Maybe after lunch in Breckenridge a ride on the alpine slide down the ski slopes and then some window shopping in town. This about a 250 mile drive.

So please let us know your thoughts on a 3-day GPSL and your interest in the Wednesday tours. We'd be pleased to answer questions about the Monday/Tuesday trip if that extension strikes your fancy.

Freddy,

You could start with a serial camera such as this one:
http://www.sparkfun.com/commerce/product_info.php?products_id=10061

Since it is RS232 and your modem is TTL levels you will need a level shifter
such as this one:

http://www.sparkfun.com/commerce/product_info.php?products_id=8780

ON the ground side you could hook up the modem through a USB to serial board
such as this:
http://www.sparkfun.com/commerce/product_info.php?products_id=198

With that setup in theory you could use the PC test software they supply to pull
pictures from the camera on the balloon. I didn't look at the details but you
may need a controller on the balloon to do some buffering but I believe you pull
blocks from the camera so that is probably not needed.

Jerry

8725. BASE 53 completed

Yahoo group: GPSL (2009 — 2010)
Date: 2010-10-15 17:40:18 UTC
From: BASE
Topic: 8725 Message: 8725

Dear friends,

BASE 53 was completed yesterday. New launch site near Clarks Hill, Indiana worked very well. There is a large, flat, open area with no power lines or trees to the east or south for several hundred meters.

System reached an altitude of 93,000 feet. Landing was east of Shelbyville, Indiana. Bill, WB8ELK copied Ron's (N9QGS) DominoEX22 in northern Alabama. Somewhat regrettably, the magnetic tree attraction effect returned at landing, after an absence of six flights, and the recovery required a sling-shot aided retrieval. One tracker radio and the parachute are still calling the top of the tree home, but they should come back to earth with a little more help.

The internet tracking of the APRS beacon was complicated by a strong i-gate from LaSalle, Illinois (W9MKS-15). This gate was hit by the airborne tracker from 12,000 feet on the ascent through 34,000 feet on the descent. Unfortunately this position reports were fed to the internet about twenty minutes or more after their transmission. The result was a delayed replay of the flight path which was seen on aprs.fi as an amazing return of the balloon from its landing point to a point on the track just before burst.

Our next flight is scheduled for 28 October.

Thanks for your support,
Howard, KC9QBN

Invitation has been extended based on the additional (and somewhat preliminary) details provided by Rob at EOSS this morning, which were very helpful to add some substance. I'll let you know if anything comes of it. Since John is a writer by trade, he might be able to combine this with a Colorado vacation and get a column out of it.

I sent a Find Me Spot on my near space flight this morning. We got a total of 16 position reports to the Spot satellite. One option was to download the data as a KML. I've attached the Google Earth image.

Pretty cool back up system. Thanks Bill for telling us about this.

I got a video of a balloon burst from the ground. At six magnfication, the balloon is only a few pixels wide, but you can see it disappear when it bursts. The only bad thing about it is that I bumped the camera so the balloon is located in a lens flare.

I'll edit the video and post it.

Viddler or Vimeo might be good for larger vids.

If there's a way to zoom in on the video area you're trying to show us, that might come through. Unfortunately I think YT's compression and artifacting has made it invisible on the video.

Good job, though. Like the shot of the airplane in the sky as it was launched.

Topic: 8728 Message: 8738

I also bought a SPOT but I haven't sent it on a flight yet.

One thing I wanted to do was display the last few locations on my smart phone. There is an app but the one for blackberry doesn't work on my phone. So using yahoo pipes I created the following pipe. It will display the last 5 locations on any phone with google maps or on google maps on a PC.

NOTE: There are some refresh issues that will be addressed later in this email.

To test this simply paste this ugly link into the search box on google maps (phone or maps.google.com). You will see 5 locations in my back yard.

http://pipes.yahoo.com/pipes/pipe.run?_id=c386900fbf430d8405b9e19112b24992&_render=kml&glid=0RDW6oJpmYBqxAXMY225uknXLFVmhDnuC&dummy=1

Simply replace the glid= number with the glid number in the shared spot page.

Now for the refresh issue. Google maps caches the URL search for 30 minutes. If you put in a previous URL it will use the old data and not refresh it. To get around this I added the dummy value at the end of the url. This value is not used but if you change it google thinks it is a new URL and refreshes the data.

I figure this will be handy for that final hike through the desert or finding my care in big parking lots:)

I am going to look into doing something similar for APRS data. I think I have a source of the data.

If someone knows of something that already exits for this let me know.

Jerry

It all depends on your point of view. Trail Ridge road might be Trail
Edge Road for some!

I know the road from Idaho Springs to Central City - AKA Virginia
Something road, AKA Central City Parkway (now), was often called OMG
road (Oh My God road!) It was most fun after a snow storm and caused
premature aging to both humans and steering wheels.

I'm all for the three day event. I toured Spark Fun this past summer and really enjoyed that. They have a nice lab that maybe could be utilized for a building project.

I'm planning on staying in Colorado a couple of days after the event, and hope to climb another 14er maybe Monday or Tuesday. If anyone else is interested in joining me on that, contact me off list and we'll check into the viability.

8742. Re: [GPSL] GPSL 2011

Yahoo group: GPSL (2009 — 2010)
Date: 2010-10-20 03:01:47 UTC
From: Mike Manes
Topic: 8723 Message: 8742

I just offered that clarification for those in the group who may wish to look up the route online.

I've also been over OMG (Virginia Dale Rd?) road, and yeah, not in a Winnebago even in nice wx :=P !

There's a brand new 4-lane road running from I-70 just E of Idaho Springs to Central City - I think it's aka Central City Pkwy. Much more civilized drive!

BTW, OMG road is one of a class of roads called ledge roads. One neat one is the road to the 14,250' summit of Mt. Evans - it's only open in the summer, and is actually paved, despite being just a narrow 2-lane. Real fun encountering an 18-wheel tractor coming the other direction - not!

The GPSL folks may also enjoy driving to the summit of Pike's Peak overlooking CO Springs. It's dirt, but much wider than the Mt. Evans road.

Both peaks are GREAT sites during microwave contests! I earned VUCC in one weekend with my 10 mW 10 GHz Gunnplexer rig and a 19" dish on Evans.

If you take the Trail Ridge Rd trip, to get off the beaten path a little you might also consider taking US34 west out of Estes Park for 7.3 miles (Horseshoe Park) (40.404778/-105.624639) and take Fall River Rd. It is 9.8 miles long and ends at US34 at Fall River Pass (40.441044/-105.755369) back on US34. The road is rough in places so I wouldn't recommend it for low clearance vehicles.

73 Harry KC5TRB

....Trail Edge Road was spectacular last year, I highly recommend taking the trip.

Hmmm... Cell phones are not supposed to be alive in the payloads per FCC rules, and are these newbies talking to the FAA at all?

This type of hype is the stuff that will hurt our hobby.

Or with all the press these cell phone flights are having, they may not
even know that Amateur Radio Exists.

One thing that somewhat bugs me about that flight anyway from the first
time I seen the video, is how everyone is making such a big deal about
the Father and Son aspect.

From everything I saw on the video 99% of it was the fathers
excitement. The "Son" was more interested in the video camera shooting
the story footage. And maybe the launch itself.

He seems far too young to really understand whats going on. What maybe 5
years old?

I'll second that, except that the definition of "low clearance" would have to be very low. My wife and I drove it twice in a BMW 540 in the summer of 2002 with no issues at all. It is gravel though, so if there has been a lot of rain it may not be recommended in a car with lower clearance and less aggressive tires.

But it's definitely a scenic trip and worth going up that way and returning via the paved route.

Looks like the Paper Airplane Released Into Space balloon launch orchestrated by the British tech blog The Register has been pushed back a day... it's been mentioned before on this list, but not for a while, so I thought I'd bring it back into the collective consciousness. Here's the latest story, which contains links to all of the details:

Talk about FB PR for a newbie launch team!
It's intriguing that these Limeys MIGHT be using the ham bands for
APRS tracking - or not.

The Register started this in response to this launch:
http://news.bbc.co.uk/2/hi/uk_news/england/wiltshire/8171619.stm It is a BBC
story about someone that launched a slice of cheese into space. The register's
first story here: http://www.theregister.co.uk/2009/07/29/space_cheese/

Since then they have gotten quite a few sponsors. Big Red Bee has provided at
least one GPS/APRS module for the plane.

Here is a nice article on the balloon launch failure down in Australia a while back. Based on my limited experience and screwups with these little balloons, I would have to agree that while launching a balloon seems easy, its really easy to mess up. Its even easier with these bigger ones.

Definitely read the report for the real story, the article is nearly useless as a summary.

The bottom line is that the NASA balloon program didn't have a comprehensive safety program because (a) it'd drive up launch costs too far, and (b) nothing significant has happened yet, so it must not be necessary to have one.

Here's the basic story line. Everything is normal through fill and initial release of balloon. Crane driver takes an 'odd' path trying to get under balloon, introducing unexpected loads on release mechanism, can't release balloon from crane due to these loads. Crane driver gets to airport fence and has to stop with balloon still not released. Can't abort launch there due to spectators in the way outside of fence, so driver directed to back up. This introduces even more load on mechanism, resulting in unexpected full release. Payload swings through fence and into cars.

Unforecasted winds were not a cause of the accident, nor were winds considered out of limits.

In my humble opinion a BIG difference on regard this Mishap and several others NASA had before with balloons (even as catastrophic as this one) is the level of widespread and instant coverage the incident received -ergo the bad publicity-.

In the past the agency never published openly the results of the investigation boards ... this time the circunstances aforementioned forced them to do so.

Greetings

Hi,

Well, from the earlier videos, the wind was pretty brisk, and >nowhere< in the NASA report did I see the wind velocity noted; just its direction. And many of us know how spooky a windy launch can be.

Had there been near-calm conditions, even though the "Tiny Tim" launch crane was way out of position, the balloon would not have taken on that rather acute angle from vertical; it would have made its way to a near-overhead position above the crane. So the safety cables would not have been overstressed and the launch could have been terminated well without coming anywhere near the airport boundary.

Note from the earlier video (I assume it was taken at that launch), that the wind was dead calm after fill near sunrise. But there was a 1-hour launch delay called early on, and a further 10-minute delay to clear the airspace, during which time the wind came up.

It's definitely a good read. But beware: it could induce a visceral urge to take up a less exciting hobby, like coin collecting ;=(Sure glad we in ARHAB don't have to deal with those huge "Buick with 4 scientists" payloads!

From: wb8elk@aol.com
Topic: 8756 Message: 8763

On our first flight of a 19,000 cubic foot zero pressure balloon, it was dead calm at our launchsite....absolutely perfect conditions. It was at that point that our chief rocket scientist remembered that he had left a key component of the experiment back on the bench of his workshop (about a one hour round trip). This was to be a test of our ignitor system for our future Rockoon missions so we deemed it necessary to sit there holding a large fragile balloon crossing our fingers that the calm conditions would hold up for an additional hour.

Mother Nature doesn't miss an opportunity to play with these big balloons for very long and true to form, the winds starting getting pretty dicey as the clock ticked. Then she hit us with all she had....big gusts (10 mph +) started to pommel the balloon as we frantically scurried around the balloon trying to keep it from hitting the rough former runway. It bounced off our heads as we made futile attempts at trying to keep our bodies between the balloon and the jagged asphalt. Our rocket guy arrived to see the balloon smash into the runway during a 15 mph gust that ripped a nice big 2 foot gash about halfway up the envelope.

Then by some miracle, seeing that her job was done, Mother Nature went off to play with some other fragile device and it became suddenly calm again. I tried to patch the gash with strips of clear packing tape on the inside and out....topped the balloon off with some more helium and we let it go with a cheer. Fifteen seconds later, the APRS tracking payload's antenna caught on a loudspeaker pole used by the county fair....fortunately it wasn't a live power line but looked like one. It sat there for 10 minutes (I later called this our "post-launch" testing phase). A 30-foot telescoping pole and hook did the job and finally set our fateful balloon on it's journey.

However, the packing tape fix let loose at about 30,000 feet and it came back down to earth in western Georgia. A woman was doing her dishes and watched the whole thing come down in her Kudzu patch behind her house. She immediately called the police, TV and radio stations excitedly proclaiming that a UFO had landed in her back yard. Five minutes later our chase crew arrived (many of them look like space aliens). It took quite some time before they could convince her to let them do the recovery.

8767. ARBONET Flying tomorrow (Saturday Oct 30th) at 0900 CST

Yahoo group: GPSL (2009 — 2010)
Date: 2010-10-30 01:11:53 UTC
From: Michael Willett
Topic: 8767 Message: 8767

ARBONET is flying a 600gr balloon out of Hillsboro, TX tomorrow at 0900 CST.

The balloon will be flown to natural burst.

Aboard will be a Simplex Repeater, APRS, CW beacon and Voice Beacon.

The Voice Beacon will be necked into the balloon again, taking measurements of envelope pressure, internal temperature and external temperature, reporting information as a synthesized voice.

The voice beacon will be operating in the 70 CM band.

The Simplex repeater is a 30 second record / 30 second playback with courtesy timer tone unit operating in the 2M band.

The CW beacon is also in the 2M band.

We are flying APRS, a MicroTrak-300 as K5ARB-11 beaconing every 60 seconds and likely a second MicroTrak-300 APRS unit reporting as K5ARB-10 at 301 second intervals on 144.390MHz

We will be flying an inverted parachute below the payloads for return after burst.

You can follow field updates on twitter, http://www.twitter.com/ARBONET

Or follow us on the APRS system. See http://WWW.ARBONET.NET for fast facts details on frequencies and location.

Thanks for keeping everyone up to date.
We had issues with tracking the plane sadly. But it did release at height and we did get it back, surprisingly with little damage.
We got forced into doing it on Thursday as I was flying back to the UK on Friday.

Not sure how I got back with no problems considering the kit I was carrying, and the Terrorist activity, on the day.

8771. ARBONET Payloads Recovered after a great flight. (Saturday Oct 30th) at 0900 CST

Yahoo group: GPSL (2009 — 2010)
Date: 2010-10-30 20:52:08 UTC
From: Michael Willett
Topic: 8767 Message: 8771

The ARBONET flight went off without too much trouble this morning.

Last night the voice beacon started to act up, likely due to battery limitations. So the voice beacon did not fly this trip.

However, all other facilities seemed to work fine.

The balloon was loaded a little hot for a quicker ascent and a smaller 3' rather than 5' parachute was used to shorten descent. This resulted in a landing zone short of the simulated target.

The payloads landed in a conservation area and a local person already loaded the payloads into their pickup prior to our arrival. A quick exchange by David, Tommy and Doug with the local person and the payloads were in our hands.

The K5ARB-10 was set for 301 second transmissions and appeared to work 100%.

The K5ARB-11 was set for 60 second transmissions and occasionally did not report altitude, but was nearly 100%.

The simplex repeater carried some traffic and the CW beacon was heard throughout the flight, both seemed to work great!

The video camera on board with the APRS beacon K5ARB-10 captured a rough ride through the entire flight past 70K ft, but also captured an excellent view of the balloon shards against the black of space, a spectacular frame of video.

It was a small team of 4 of us chasing today. David and Tommy brought their exceptional experience from the NTXBP, Doug from McKinney and myself from Granbury. The equipment worked well in almost all respects, the chase was quite fun and the recovery uneventful - like we all wish most of our flights could be.

You can go to twitter at http://www.twitter.com/ARBONET for a play-by-play report of Doug's view on today's flight.

Nice job, Steve! And great trick effecting a recovery absent in-flight
APRS. Just like the salad days of ARHAB, pre-GPS.

I was wondering if it were you yourself on the chase.
All I saw on aprs.fi during descent was your mobile. I guess traveling
thru the EU nowadays doesn't require a passport any more.

New FAA rules in the US obviate dropping a glider from a balloon, although
it appears that a steerable, modified conventional parachute with just one
control axis is exempt. Just haven't figured out how to make one like the
US Army's MC1-1C yet.

Did you have any problems bringing the Vulture back home as checked baggage?

8773. What does the ICAO 230N (50lb) impact force mean?

Yahoo group: GPSL (2009 — 2010)
Date: 2010-10-30 21:39:23 UTC
From: steve@btinternet.com
Topic: 8773 Message: 8773

The ICAO document on unmanned free balloons says:-

"Uses a rope or other device for suspension of the payload that requires an impact force of 230 N or more to separate the suspended payload from the balloon."

Can anyone explain exactly what this means? - is it simply about rope/cord with a breaking strain of greater than 50lb (230N) - or does it mean something else? - and if so what test situation are they describing.

Steve

I had APRS on the balloon as well G6UIM-11. The plane I ended up direction finding, until I got a good enough signal to decode the APRS data. We were very lucky where everything landed. And the payload came down with pretty much all of the 1.5kg balloon attached. I was a bit worried about the 60mph drop after balloon burst.
Sadly got very little usable data from the plane, but keep an eye on the register for video of the plane release.

I was on the chase as G6UIM-9 that was via a mobile dongle which was a bit hit and miss connection wise.

Had to take my passport and if in Spain the expect you to have id on you. Had no problems taking all my kit on the plane.

The Spanish authorities were very ok with what we were doing, we were in the middle of nowhere and had no problem with them.
The locals thought it was all fantastic.

Nice job, Steve! And great trick effecting a recovery absent in-flight APRS. Just like the salad days of ARHAB, pre-GPS.

I was wondering if it were you yourself on the chase.
All I saw on aprs.fi during descent was your mobile. I guess traveling thru the EU nowadays doesn't require a passport any more.

New FAA rules in the US obviate dropping a glider from a balloon, although it appears that a steerable, modified conventional parachute with just one control axis is exempt. Just haven't figured out how to make one like the US Army's MC1-1C yet.

Did you have any problems bringing the Vulture back home as checked baggage?

Hi Steve,

As with FAR-101, I've never found a definition or test spec for "impact force". But it's NOT tensile strength, as so many fellow ARHABer have learned the hard way. The intent of the vague requirement is to ensure that a mid-air between the balloon lift line and an aircraft doesn't leave the line intact. EOSS uses 240 lb tensile woven nylon for its exempt flights, and 500 lb line for it's "heavies". We're quite confident that the 240 lb line conforms to the intent of the rule, since it broke at a knot just from the hefty tug of one of our trackers trying to pull the payload line free from a tree.

BTW, use nylon rather than Dacron; the latter has no "stretch", and thus risks being (as has) broken during PBC, where flailing payloads are abruptly decelerated when they get to the end of the line. Woven nylon will stretch like 150% before reaching its tensile limit.

The main payload was fine, and it had a redundant beacon not that it was required. The main problem was the camera payload blocked the plane's gps, the plane got a lock not much before landing. Getting the plane back was the thing we most wanted to do

But on the whole I think a good launch.

I had to fight off a lot of locals to get to see the laptop tracking, one pulled a sickie to help us out.

It would have been nice to track the planes flight, but we have I think managed to raise awareness of amateur balloons and amateur radio.

My first one but hooked now

Hi All,
We're looking at Zigbee to talk to temp sensors in our ZP balloons this year. I've seen lots of zigbee talk on this list, but often the frequency used isn't mentioned. I've read a lot of the past posts regarding it, but I was wondering if anyone could just comment on your experiences with Zigbee de-sensing the GPS receiver. I.e. which freq of zigbee tx created the problem, and how far was it from the GPS and 2m

Thanks,
Dan

When I go out Paul I have a aluminum 2 piece pool cleaning tube that extends from about 11 for to 21 foot and also what they call lay up fiberglass sticks that the electric company use in 6 foot tubes that go together for 30 feet. And don't forget Bill Brown's WB8ELK favorite tool Duct Tape. Both have hooks on the end made out of #6 solid wire and they will snag strings real good. I have also heard of some using a potato spud gun with string attached. Good luck Mike

Paul,
Here's what goes with me on every tracking and recovery:
1. A 40 foot extended Wonder Pole (http://www.wonderpole.com/wp640_630.html) with two special ends. One is a hook made from 3/8 inch threaded rod. The second is an old pruning saw blade.
2. The EZHang system (http://ezhang.com/index.php?_a=viewCat&catId=1) (a Hyperdog Sling Shot, Zebco 33 reel, one ounce lead shots, and tennis balls, 250 feet of 300 pound test line).
3. A rope saw (mine is a Sears model that is no longer available, but here is a similar product http://www.treehelp.com/itemdesc.asp?ic=GM-CS-48)
4. Corona Clipper Razor Tooth Pruning Saw
5. An assortment of extra ropes (approximately 200 feet) for extending the rope saw and/or pulling on limbs/payload strings with a stronger rope.
I do have a chain saw and axe that I have brought to recovery sites on the return trip, if chain saw is a viable option. On a couple of occasions, I have hired a tree climber to recover the flight system. In my experience, three hours to get out of a significant tree is not too bad. My son and I spent seven hours on Saturday (after three hours on the flight day) working on retrieving the remaining radio and parachute from BASE 53. Still need to make one last return trip (ran out of daylight) to finish the retrieval.

Dan,
We have used MaxStream (now Digi??) XBee Pro operating at 2.4 GHz with no problem for any of our radios (typically some version of Byonics MicroTrak) or GPS (Garmin 18). In some cases, all three devices are in a single styrofoam box.
We also have flown a configuration that has the XBee Pro, Garmin 18 and a FreeWave 900 MHz spread spectrum unit in the same box.
I have never experienced any problems with interference or de-sensing.

Dan,

I echo Howard’s experience. I have flown both high and low power level Digi ZigBee 2 GHz modules that were mounted within 1” of Garmin GPS-15 and uBlox GPS units (and within 3” of their antennas) without difficulty for over 5 flights. In all cases I used ZigBee units with integral antennas, both the patch and wire version. Based on bench tests and field use I have also not seen any indication of 2M receive sensitivity loss in the presence of 2 GHz ZigBee either.

I utilize pretty standard foam core compartmented enclosures. I do however place a mu-metal foil shield between the compartment housing the GPS antenna on the top of the payload and the lower compartments housing the rest of the gear. No fancy feed through for the GPS coax is used. I got into this habit from my 433 MHz balloon-bus days where I did have issue with GPS receiver interference which was ultimately traced to the 433 MHz getting into the GPS antenna internal preamp.

In the past I have had to resolve interesting 2M birdies generated from my serial data lines within the payloads so I would suggest checking for those carefully.

> I utilize pretty standard foam core compartmented enclosures. I do however place a mu-metal foil shield between the compartment housing the GPS antenna on the top of the payload and the lower compartments housing the rest of the gear. No fancy feed through for the GPS coax is used. I got into this habit from my 433 MHz balloon-bus days where I did have issue with GPS receiver interference which was ultimately traced to the 433 MHz getting into the GPS antenna internal preamp.

From: Tim
Topic: 8781 Message: 8792

I have a question for the list...

How long is the distance from your balloon to your payload? I know everyone will have a different answer but in my mind longer is better. If your parachute gets caught in a 50' tree and the distance is between the chute and payload is 50' then at worst you loose the chute? I also think that the payload is more stable the farther away it is from the balloon, on the ascent that is. I do not have any facts to back this up so I could be way off base but it seems to be true in the scaled down tests that Brenden and I have done.

Thanks for your input,
Tim

Paul,

Here's what goes with me on every tracking and recovery:

1. A 40 foot extended Wonder Pole (http://www.wonderpole.com/wp640_630.html) with two special ends. One is a hook made from 3/8 inch threaded rod. The second is an old pruning saw blade.

2. The EZHang system (http://ezhang.com/index.php?_a=viewCat&catId=1) (a Hyperdog Sling Shot, Zebco 33 reel, one ounce lead shots, and tennis balls, 250 feet of 300 pound test line).

3. A rope saw (mine is a Sears model that is no longer available, but here is a similar product http://www.treehelp.com/itemdesc.asp?ic=GM-CS-48)

4. Corona Clipper Razor Tooth Pruning Saw

5. An assortment of extra ropes (approximately 200 feet) for extending the rope saw and/or pulling on limbs/payload strings with a stronger rope.

I do have a chain saw and axe that I have brought to recovery sites on the return trip, if chain saw is a viable option. On a couple of occasions, I have hired a tree climber to recover the flight system.

In my experience, three hours to get out of a significant tree is not too bad. My son and I spent seven hours on Saturday (after three hours on the flight day) working on retrieving the remaining radio and parachute from BASE 53. Still need to make one last return trip (ran out of daylight) to finish the

retrieval.

Hi Paul,

EOSS-158 is flying this weekend, 11/6, just a few days shy of the 20th anniversary of EOSS-1 which launched 11/17/1990. That works out to 7.9 flights per year. But EOSS-100 flew on our 15th anniversary, just 5 years ago - EOSS's pace has since bumped up to 11.6 / yr, thanks in a LARGE part to Chris Koehler of Colorado NASA Space Grant.

So get off your keister, Paul :=)

However, I can't remember the last time any EOSS flight got media coverage. Coulda been in the Tri County Courier out of greater downtown Deer Trail, CO, back in our 2-digit flight number days.

Tim,
The distance between the balloon and parachute is generally twenty feet. Typically, the distance between the parachute an the first payload box is about eight feet, with subsequent payloads separated by similar distances. However on descent, the balloon fragment usually hangs below and to the rear of the flight train making the overall length of the system shorter.

Of our 53 flights, 15 have ended with tree landings. Two were in a fence row, but the rest were either into multiple trees or in the middle of an extended set of trees. It is my opinion that a long flight string, from the parachute to the lowest payload makes it more problematic when the system lands in a tree top. I have had two tree landings where the lowest payload pod or pods are dangling free. It is more common for the lowest pod to encounter the trees first and the rest of the flight string to land according to the prevailing wind. Here is a link to a photo from the landing of BASE 34.
http://www.depauw.edu/acad/physics/base/images/BASE34landing.jpg
If I can keep the total payload under six pounds, I will put all of my packages (assuming no radio interference problems) in a single bundle below the parachute. This reduces the height of the descending system and slightly reduces the cross section for encounters with the trees.

I've created a webpage of links so anyone can track NearSys flights onlne.

http://nearsys.com/arhab/tracking.htm

I'll keep updating the page. I plan to continue flying a SPOT tracker on each mission. My share page link is located on my tracking page.

It looks like I ony send a single message from yesterday's flight. I was trying to set it to transmit every 10 minutes.

8802. Launch this Sunday 11/07/2010

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-02 01:47:26 UTC
From: Brenden Geary
Topic: 8802 Message: 8802

I am launching again on Sunday 11/07/2010. I plan to stream the launch live to the web if you have nothing to do Sunday morning take a look. The stream will be only from the ground not the payload. The launch should be at sunrise, around 8am PST because of the time change. The payload will contain a HD video camera, praying for some great footage and it back of course.

Here is the link for the video...

http://brendengeary.squarespace.com/live-video/

Taylor University will be launching Two 1200gm balloons, the ASTRO launch will be our 250th launch.

Flight #: 250
Flight ID: 2010 Fall ASTRO
Date: 11-06-2010
Time: 9:00 AM
Launch Site: Taylor University

APRS: 144.390 KC9QCD-11

Flight #: 251
Flight ID: 2010 Fall CHEM
Date: 11-06-2010
Time: 10:00 AM
Launch Site: Taylor University

APRS: 144.390 KC9QCD-12

HawkEye Spec:
Analog channels: 25 to 250
High speed user data bus interface (ZigBee 2.4Ghz)
Three axis GPS configuration (20Hz sampling)
Dual high speed Uplink / Downlink RF module 900Mhz ISM (Secured Constellation MESH Network)
Controlled Ascent / Descent rates
Altitude Hold (+- 500m)
Stabilized targeting platform (+-3 Degree)

From: wb8elk@aol.com
Topic: 8779 Message: 8806

Dan,

Last August I flew a 100 milliwatt Zigbee PRO XSC unit on 915 MHz sitting about 6 inches from my Inventek GPS board and I saw no desense problems...in fact I managed to get quite a few direct to ground telemetry strings from the Zigbee unit in the balloon using it's rubber duck antenna to my 8 dBi patch antenna and another Zigbee PRO unit on the ground from over 20 miles away....and in it's worse antenna pattern for the balloon since I was directly underneath it while it was 20 miles above me.

On Nov 1, 2010, at 11:56 AM, Meer, Stephen wrote:

Dan,

I echo Howard’s experience. I have flown both high and low power level Digi ZigBee 2 GHz modules that were mounted within 1” of Garmin GPS-15 and uBlox GPS units (and within 3” of their antennas) without difficulty for over 5 flights. In all cases I used ZigBee units with integral antennas, both the patch and wire version. Based on bench tests and field use I have also not seen any indication of 2M receive sensitivity loss in the presence of 2 GHz ZigBee either.

I utilize pretty standard foam core compartmented enclosures. I do however place a mu-metal foil shield between the compartment housing the GPS antenna on the top of the payload and the lower compartments housing the rest of the gear. No fancy feed through for the GPS coax is used. I got into this habit from my 433 MHz balloon-bus days where I did have issue with GPS receiver interference which was ultimately traced to the 433 MHz getting into the GPS antenna internal preamp.

In the past I have had to resolve interesting 2M birdies generated from my serial data lines within the payloads so I would suggest checking for those carefully.

Hi All,
We're looking at Zigbee to talk to temp sensors in our ZP balloons this year. I've seen lots of zigbee talk on this list, but often the frequency used isn't mentioned. I've read a lot of the past posts regarding it, but I was wondering if anyone could just comment on your experiences with Zigbee de-sensing the GPS receiver. I.e. which freq of zigbee tx created the problem, and how far was it from the GPS and 2m

Thanks,

Dan

Howard,

That picture awful, it couldn't have landed in a worse spot. I see your point... you want the payload footprint to be as small as possible to possibly slip past the trees. Have you put a video camera in any of your payloads? If so did you use the same setup? If you would like to check it out Brenden will be streaming his launch live at 8am pst Sunday 11/07/2010.

Subject: Re: [GPSL] Trees

Tim,

The distance between the balloon and parachute is generally twenty feet. Typically, the distance between the parachute an the first payload box is about eight feet, with subsequent payloads separated by similar distances. However on descent, the balloon fragment usually hangs below and to the rear of the flight train making the overall length of the system shorter.

Of our 53 flights, 15 have ended with tree landings. Two were in a fence row, but the rest were either into multiple trees or in the middle of an extended set of trees. It is my opinion that a long flight string, from the parachute to the lowest payload makes it more problematic when the system lands in a tree top. I have had two tree landings where the lowest payload pod or pods are dangling free. It is more common for the lowest pod to encounter the trees first and the rest of the flight string to land according to the prevailing wind. Here is a link to a photo from the landing of BASE 34.

http://www.depauw.edu/acad/physics/base/images/BASE34landing.jpg

If I can keep the total payload under six pounds, I will put all of my packages (assuming no radio interference problems) in a single bundle below the parachute. This reduces the height of the descending system and slightly reduces the cross section for encounters with the trees.

We have had more fortune than some of Howard's exploits - in 40-some flights we have had only two tree landings (and Paul was there for one of them). Most of eastern Nebraska and western Iowa is blessedly free of trees when compared to the Midwest or South.

Even so, we carry an extensible pole (believe it's primarily for painting, also used by an NSTAR member to hang Christmas lights) with a hook on the end. On the first tree landing flight, Paul was able to climb the tree some distance and snag it with a short length of the pole. The very next flight, we landed in a tree yet again about 30 feet up. We were just able to snag one of the payloads and bend the entire tree over (they were tall but spindly) to pull the entire flight train out.

I have had thoughts of including ~50 ft of line terminated with a lead weight hanging from the bottom payload. The idea is that that line would perhaps hang down within easier reach and allow the recovery team to pull the flight string out of the tree. Or, if one were really good at such things, have the line spooled inside a payload and released when it detected that it's landed. The weight would hopefully fall somewhat cleanly through the branches to ground level. Of course Murphy could play havoc with either solution and you end up still needing one of the other methods.

A chain saw with sufficient gasoline and oil is probably the most reliable solution.

Mark,

We've been toying with just such a concept called "Rapunzel"....where the lead weight on a spool is released after landing in hopes it will make it way to the ground.

- Bill WB8ELK

We've used the chain saw method on many occasions (although tree-climbing engineering students also are quite effective)....we land in trees about 50 percent of the time... or in lakes.
The only drawback to the chainsaw method is that the landowner sometimes asks us to cut the tree up in 2-foot lengths and stack it up near the house.

Anyone thought of building a tree-climbing robot??

CNSP flight is canceled for 11-4-2010.

UPS has delayed our balloon shipment to 11-4.They have had our shipment at their Oakland facility since 11-2 and have not kept the shipment moving to San Jose; we should have received the balloon today 11-3.

The weather conditions will not be favorable for launch the next few days after 11-4.

We will post information on our next launch attempt at
http://www.CaliforniaNearSpaceProject.com

From: BASE
Topic: 8816 Message: 8816

Dear friends,

The T -24 hour GFS wind model has brought an interesting twist to tomorrow's flight. The winds have decreased at almost all altitudes (above surface) and rotated slightly northward. End result is a set of predictions centered on a landing just outside of turn three at the Indianapolis Motor Speedway. There'e no race there tomorrow, but the 10 mile radius landing zone is daunting to say the least (downtown Indianapolis, the airport, etc.). Of course, that sort of landing zone could bring additional publicity to ARHAB :)

This may lead to a slow climb flight which is always exciting (remember BASE 20 to Lake Erie??) with strong surface winds.

I'll run new predictions on Thursday morning.

The flight will also carry the 900 MHz spread spectrum transmitter. The APRS radio is a MicroTrak 300 mW on 144.39 MHz with the W9YJ-11 call sign using WIDE 2,1. An additional backup tracker from Trey, KC9QOV.

Thanks for your support,
Howard, KC9QBN

Turn 3 seats at IMS are no good as you have to look into the sun too much!
Sitting in turn 2 or 1 would put the sun at your back for a better view of
the landing!

All the above is tongue-in-cheek, of course. I enjoy watching your flights,
Howard!

Dear friends,
The latest wind predictions still have a Greencastle launch resulting in an Indianapolis landing. As a result, we will move the launch site to Northmont Schools, Crawfordsville, Indiana (40.12 N, 86.91 W).
Launch will probably be a little bit later than 1700 UTC.
Thanks for your support,Howard, KC9QBNBASE DePauw

From: L. Paul Verhage
Topic: 8819 Message: 8819

I posted video taken by the near spacecraft of my last flight. I wanted to see how much the BalloonSats would bounce around, unfortunately, the camera was shut off just after balloon burst (I wanted to see the effects of post-burst chaos and it was probably what shut me down). In the few seconds of video at the end, you can see modules spin what looks like a 360.

It's a shame, I would have really liked to have video of the tree snatching the poor, innocent near spacecraft out of the air.

Still photos from the payload will be on the site tomorrow. The pilot still recovering from the spin :-)

Although the coverage was light hearted, and obviously we had a laugh putting a pilot onboard. We were very serious in construction. And the point was to see if an unguided paper plane could make it down from 50 - 55,000ft.

Ok it released at 89,500ft due to unknown circumstances.
My local paper has picked up on it, I did try to promote balloons and amateur radio to the reporter, but on the grounds the reporter asked if we went up on the balloon, I don't hold out much hope.

I have a 5W 2M high altitude tracker with Li-Po battery, that I am prepared to loan, would be nice to see it get more use.

BASE 54 went smoothly today. Winds at launch were not too difficult. We did carry a second APRS beacon using KC9QOV-11. 600 gram balloon took 6 pounds of payload to 86,000 feet. Soft landing in a harvested field on the southern edge of Gas City, Indiana.

Geiger counters are still recording. Data downloaded tomorrow.

Hi Steve,

Well, you guys and the PARIS project did bring ARHAB to the attention of - pardon - geekdom, and that's how this hobby grows. Those who seriously ponder doing their own flights quickly learn the limits as well as the tricks and kinks once venturing into balloonacy.

One of the tricks is that "line of sight is a magic thing", such that even a QRPP 2m beacon is still full quieting 160 km downrange. And that some battery chemistries survive the deep cold of the tropopause better than other. LiSO2 primary cells are the king there, with Li-ion hanging in down to below -15C. But the polymer in LiPO cells gets real viscous below 0C, so the internal resistance goes way up.

Once the payload is on the deck, however, more ERP is nice to have in order to initiate a DF towards recovery if one is way out of position at landing.

Now, at normal ascent rates, it doesn't take much thermal insulation to keep the sensitive bits of electronics comfortable. But during descent, airspeed rises rapidly to upwards of 200 kph, so convective heat transfer becomes quite effective; and further, all that cold outside air now infliltates through any crack. This phenomenon has been observed many times in ARHAB payloads, and may be the root cause of loss of APRS reports during descent. And one descends thru a cloud, condensation can form on the chilled bits.

Another cause of post-burst loss of APRS is a fragile antenna or feedline (PVC simply shatters under stress when chilled below -30C). That sort of failure is easy to discover upon recovery - unlike the low temperature issues.

Murphy has plenty more tricks to play, but learning through experience is longer lasting.

We all have those sea sickspinning videos from our flights. I loaned a small video camera to a group that was doing a flight. One of the group grabbed a series of those spinning frames and used Microsoft ICE to knit them together. Here is the result http://www.flickr.com/photos/teamdroid/4936935476/

Imagine what you could do if you had decent images to start with. These were from a $20 640x480 video camera.

The video was unwatchable. The static image is made up of about 100 frames grabs from the video. Those are stitched together into one large (2265 x 1923) panoramic view.

I haven't used it but Microsoft ICE (free) takes a bunch of images and stitches them together into panoramas.

Hi Joe,

The plane flew about 23km, that's a straight line from release point to
landing point, I very much doubt it actually flew a straight line. The
payload and plane landed aprox 6km apart

Still photos from the payload will be on the site tomorrow. The pilot still
recovering from the spin :-)

Although the coverage was light hearted, and obviously we had a laugh putting a pilot onboard. We were very serious in construction. And the point was to see if an unguided paper plane could make it down from 50 - 55,000ft.

Ok it released at 89,500ft due to unknown circumstances.
My local paper has picked up on it, I did try to promote balloons and amateur radio to the reporter, but on the grounds the reporter asked if we went up on the balloon, I don't hold out much hope.

I have a 5W 2M high altitude tracker with Li-Po battery, that I am prepared to loan, would be nice to see it get more use.

Nice pix and narrative, and kudos on a difficult recovery.

http://www.theregister.co.uk/2010/11/03/paris_photos/

But that main payload's aerodynamics must have created some serious PBC!

8833. Panoramas using VLC and Microsoft ICE

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-08 04:23:39 UTC
From: Mark Conner
Topic: 8833 Message: 8833
Attachments: 3 described; binary payloads are missing from this source WARC

Attached are some sample panoramas made with VLC and Microsoft ICE, following up on tips posted on the GPSL list earlier. This was very easy to do with the two programs - you just use VLC to grab an assortment of still frames and then drag and drop them into ICE. You need some overlap and the more coverage around the 360 deg circle the better.

The originals are 12,000 pixels wide, about 8x the resolution I posted. They are also available (download photo to see full res) at http://picasaweb.google.com/mconner1/NSTAR10BFlightPhotos# (last 3 in album).

There were times in the past that it was pretty late in the season before GPSL dates and locations were announced. Not this year!

Here's the schedule as it stands now.

GPSL 2011: Colorado Springs, CO hosted by EOSS
GPSL 2012: Omaha, NE hosted by NSTAR
GPSL 2013: Pella, IA hosted by PENS

Thanks everyone. GPSL has grown to be quite the event thanks to your hard work

Hi all.

Hey i have been trying to crop the snap shots.

I can crop the viewable window easily so only the area I want to be visible is visible.

But when i take the snapshot. it still saves the complete un cropped view. is there something I'm missing?

No, that's what it does. It will be easier to snapshot the full frame, dump
them all into ICE, then crop the resulting composite.

Hi Mark,

Yeah, tried that but the one corner is confusing the stitching process.

I'm working on a video from our last flight.
http://www.youtube.com/watch?v=h3nx_M-dfYw
the mirror was slightly too small and the lower left corner sneaks in.
And thats confusing the stitching process.

I will try to batch crop all the images next.

That program ICE is pretty amazing!

I tried to see what it would do with a series of images where the scale is constantly changing.

What i did was take from the downward looking view, right from liftoff, to 4K feet. so Buildings at 30 seconds into the flight, and then at 4 K will be greatly different in size.

It when stitching automatically re sized the images so they fit together corectly.

I saved the one i made in the photos folder on the group site under the NSS folder.

The photos near the top are the launch site images and of course the buildings were larger than the images them selves. but after stitching it reduced them all. this was 250 images.

Now you just need to add the 360 degree spin all the way up to black space. I guess I am going to have to get with the ICE bandwagon and try it myself. It looks like there is some interesting things to be done.

From: L. Paul Verhage
Topic: 8854 Message: 8854

I posted information on the new KU launch. We plan to lift off at 5:15 AM with a 3000 gram balloon in the hopes of recording sunrise in near space. I'll send up al least one video camera and will try to make a panarama out of the footage.

Thanks Mark for letting us know about this.

8855. HYSPLIT outage this weekend

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-10 19:19:04 UTC
From: Mark Conner
Topic: 8855 Message: 8855

This outage will affect those of you who use the NSV online balloon prediction program, from Friday afternoon to Monday morning.

73 de Mark N9XTN

HYSPLIT Users:

Due to a planned power outage the READY web site will be unavailable from approximately 4 pm EST (21 UTC) on Friday, November 12 to 8 am EST (13 UTC) on Monday, November 15. All forecast data from the weekend will be missing from READY on Monday until new forecasts for Monday are received.

The EDAS and GDAS archives will include the data from the weekend once we are able to update the archives from NCEP.

Thank you for your continued support.
NOAA ARL HYSPLIT Development Team

8856. BASE 55

Yahoo group: GPSL (2009 — 2010)

From: BASE
Topic: 8856 Message: 8856

Dear friends,

BASE 55 is preparing for launch on Thursday, November 11. Launch Time will be about 1800 UTC (1 pm Eastern Standard Time). The wind pattern has shifted the launch site to the east. We will release from the Cascade High School complex (39.66 N, 86.58 W) near Clayton, Indiana.

The 1200 gram balloon will carry about 10 pounds to a burst altitude of 90 kft. Target ascent rate is 1000 ft/min. Current landing prediction just south of Charlottesville, Indiana (39.76N, 85.61W).

Tracking radios include the 900 MHz spread spectrum system and APRS on 144.39 MHz using W9YJ-11.

Thanks for your support,
Howard, KC9QBN
BASE-DePauw

8861. BASE 55 completed

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-11 22:48:39 UTC
From: BASE
Topic: 8861 Message: 8861

Dear friends,

BASE 55 was completed today. Launch was delayed by the need to produce a new DB-9 power plug for the 900 MHz radio. Launch did occur at 1825 UTC from the Cascade Schools, Clayton, Indiana (39.66N, 86.51W). Carried 10.25 pounds on the 1200 gram Helium balloon. Landing in a small corn field just south of County Road 200s (Weber Rd.) and west of State Road 9 just south of Greenfield, Indiana(39.75N, 85.76 W). Landowner was home and gave permission to recover. We had a visual on the descent from more than 6000 feet agl.

The APRS radio was not quite as effective as on previous flights. All other systems appeared to work without problem. I apologize for beaconing the ground test of the APRS radio to aprs.fi.

If we had kept the launch site in Greencastle, it appears that we would have landed in the interchange between I-65 and I-465 on the south side of the Indianapolis metropolitan area. We did fly over the Indianapolis International Airport for about five at altitudes ranging from 37-41 kft.

Our flight operations are entering the annual pause for the "Explosively propelled projectiles at Bambi and friends" season in Indiana. We may fly again in early December depending on the data collected during the flight from the Geiger counters. The data run will continue (for ground level comparison) for another six to ten hours.

Thanks again for your support,
Howard, KC9QBN

I wanted to show someone a video of one of our balloon flights.

But he doesn't have access to the net at work and dialup at home so that like kills the possibiluity of watching you tube.

So the canon camera makes .avi files when it's recording. Si i took my finished video, saved it as an .avi, and then placed it on the SD card, in hopeing that I can then play him the video using the camera.

But it doesn't show up.

anyone have an idea as to why?

Attachments: 1 described; binary payloads are missing from this source WARC

I was trying to figure this out a few years back.

I thought it might be related to the thumbnail issue. If you format your card, take one movie and then dump the results to the computer you'll have a movie named say, MVI_1234.AVI and also a second file MVI_1234.THM. The THM file is a thumbnail of the movie which is displayed inside the camera so you can see a visual representation of the movie clip and select and play it. So, I took an old movie recorded on a Canon camera, created a THM file (it's a JPG with a different extension) from the still frame of the beginning of the movie. Loaded both into the camera and voila, nothing. The thumbnail showed up as a question mark and if you selected it, you did get to see the image inside the thm file, but you could not click it to play.

I did some research and as you might imagine, this was a popular topic (still is). Everyone was not having any success taking movies and loading them back into the camera for playback. Folks even called Canon tech support and they had no answers. The general consensus is that the camera writes some type of semi-proprietary EXIF data to the THM file that links the tHM to the AVI and allows the playing of the video.

Perhaps someone has come up with the solution. I looked but was unable to find any solution on a fairly cursory exam of google results.

Too bad as a camera is the ideal platform to play back movie clips. And, it seems ridiculous that I can't take a video out of my camera, and place it back into that very same camera a minute later without the THM file and not be able to play it. If I were canon I'd come up with some little in-camera utility that would look at videos that had corrupt THM files or missing THM files and rebuild them so you could view your vids.

I did exactly the very same step by step logic procedure you described
below.

I even ripped apart a thm file in notepad just to see what was in it.
and some letters and lots of small squares!

Grrr!

8869. Flight Track Release 1.0.3

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-13 16:01:12 UTC
From: jjdemeyer
Topic: 8869 Message: 8869

Flight Track Release 1.0.3 is now available.

In this release, I added a field for an alternative call sign, and changed the real time prediction to use ascent rate as calculated during the flight. Lastly, Flight Track can export both predicted flight paths and actual flight paths to a GPX format. Flight Track is a MapPoint add-in and is available here:

http://www.surfingsatellites.orgsurfingsatellites.aspx?Page=FlightTrack.Download

The Add-In installs with sample flight data so you can immediately evaluate its primary functions. For more information, I invite you to review the Flight Track on line Help at

http://www.surfingsatellites.org/flighttrackhelp/fthelpcontent.htm

Feedback and suggestions are welcome here

http://www.surfingsatellites.org/surfingsatellites.aspx?Page=FlightTrackFeedback\&ContactSetUp=Feedback

Joe,
I have been going to try your program, it looks very interesting. I guess I need to go buy a copy of MapPoint now:)

One question, can you get input from the internet (iGate) or does it only work from a direct radio connection?

Hello Jerry!

Thanks for asking!

I have had a couple of requests for alternative data source. In the next release of Flight Track, I am planning to provide more flexibility of data sources. Presently, Flight Track accepts direct radio connection only.

Joe

Just got this in an e mail, anyone wish to try it and see if it works,?

THM is video thumbnail and it is required to play video in camera.
AVI is not an encoding, this is just container format.
You can have MPEG, MJPEG or many other encodings inside of it.
Camera can playback only MJPEG (motion jpeg) encoded data.

So you will need video editor capable to save video stream into MJPEG
encoded AVI, with WAV (PCM uncompressed) sound track.
Video should have same resolution as original.
THM is just a JPEG with changed extension, so you can save any frame of
video to JPEG and change extension to THM (there may be some problems
with EXIF) or use THM preview from any video recorded by your camera.

Hi Joe

Looks great. I get quite a few errors when Reviewing the flights at 1 packet per second. It's much more pronounced with MapPoint 2009 than with 2004. All the errors seem to indicate that MapPoint isn't able to plot the data quickly enough which makes sense since 2004 runs more quickly than 2009. Simply slowing the replay rate down to 2 or 3 seconds per packet is all it takes to make the errors stop.

I still have to toss our 2010 SABRE flight data into the program to see how it compares with "real life". All I need to do is figure out how to cram a full time job plus time for family and friends and time for hobbies into a mere 24x7 week. Maybe I could stop sleeping. ....

I found a program, that tells you what actual type of file is inside an
AVI file.

And the canon indeed does make an MJPG.

Whereas, my AVI that is outputted from windows movie maker is DVSD.

i have been looking for a program that can convert some type of file to
a MJPG file.

but haven't had any luck as of yet.

Thanks, Bruce!

I have seen MapPoint 2004 get slow at fast Review rates as well. Thanks for the data point on MP 2009.

As you have seen, slowing the Review rate helps. I did try some simple things in this release to address this. I probably got spoiled with a newer laptop. For the next release, I expect to address this more; I want to determine if there is some optimization I can do.

Another thing you might try is turning off the real time prediction at least while reviewing. Without the real time prediction, Flight Track does not have to calculate the predicted path or display it.

Joe

8878. KU and WU Flight

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-14 04:51:27 UTC
From: L. Paul Verhage
Topic: 8878 Message: 8878

The KU and Washburn flight reached 113,000 feet. We got some photos and a 1GB video of the entire flight, including sunrise at around100,000 feet and the earth's shadow. We can see Venus above the dawn.

The GPS lost lock for 10 minutes on descent, Since the burst happened at 113,000 feet, I wonder if the parachute was giving us some problems with choatic descent.

The other problem was mud. It rained yesterday. The winds were high enough that the payload was blown 1/8 miles across a very muddy field.

I'll update by webpage shortly. I'm looking forward to makling a panaorma of dawn.

If the video reveals PBC, vent the 'chute well and dump the latex ASAP.
That might help. Making the payload enclosure look like a low-drag bomb
also helps.

8880. Internal Balloon Temp and Pressure during flight

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-15 00:48:28 UTC
From: Jerry Gable
Topic: 8880 Message: 8880
Attachments: 2 described; binary payloads are missing from this source WARC

I finally have the data on the differential pressure during a flight. This was a 1000 gram balloon. The ascent was about 1100 Ft/Sec with a burst altitude of 87,000 feet.

The pressure and temperature was measured at the end of a tube that went about 20 inches into the balloon. The tube fed the pressure to a differential pressure transducer outside the neck of the balloon.

As expected there was a peak pressure as the balloon started to inflate. This quickly started to drop off as the balloon inflated as expected.

At launch the pressure suddenly dropped 0.003 PSI. I suspect that was due to the acceleration possibly on the actual transducer. If anyone has another explanation I would love to here it.

Again as expected the pressure dropped as the diameter increased.

As the balloon approached burst the pressure did increase as expected. The increase from the minimum was about 0.008 PSI. I don't think we can judge how this compairs to the initial peak because of the offset during Ascent.

The temperature was probably as expected. During fill the internal temp was a little lower than the outside temp which can be explained by the cooling from the helium pressure change. Once in flight the internal temperature lags a little but not by a significant amount.

I think some other groups measured internal pressures and would love to know how these compared.

Graphs should be linked to this email.

Jerry

Hi Jerry,

Slick work! That pressure rise preceding burst could be used to operate a dump valve to make a latex float or to cut it away before it has a chance to foul the 'chute or payload string.

Re the pressure drop at launch: As I've observed before, it's possible that you were getting some "pitot tube" effects from airflow pushing into the ambient side of your differential transducer. This is a problem that aircraft makers have to deal with in locating their static pressure ports on the fuselage. That port is used for the altimeter, airspeed indicator and rate of climb indicator, and thus should present the ambient static pressure, regardless of airspeed. It does take some "cut and try" to get it right. This is why flight test models of new aircraft are commonly equipped with a long pitot-static probe extending some distance forward from the nose of the aircraft; that probe has proven accuracy and is independent from the test aircraft's aerodynamics. And it's used as the reference for locating both the pitot tube and static ports on the production aircraft.

The airflow at the bottom of an ascending balloon can be expected to look pretty weird. It might be possible to escape some of those effects by running a long tube to a horizontal-facing static port well below the balloon and payload string. But that tube would almost surely get twisted up in the lift line :=(.

I'll share this with everyone.

I'm attaching charts for cosmic rays, relative humidity, temperature, and ascent rate.

We observed sunrise at 80,000 feet (sooner than I was predicting) and at MET of 68 minutes.

Interesting points.
The air temperature stayed flat for 25 thousand feet. Normally we observe a peak of minimum air temperature and then it begins warming up.

The relative humidity don't produce spikes until 95,000 feet, or 15 minutes after sunrise. It's normal to see spikey RH data. I'll turn the weather station 90 degrees on the next flight to see if that helps to keep the sun off the sensor.

The cosmic rays peaked and decrease like normal, but then increase above 110,000 feet. I don't knpow if that;s normal (look at the RM-60 plot, it measures alphas, beta, and gammas. The Goldmine sensor measures only beta and gamma.

The ascent rate may have increased slightly after sunrise. However, it's not a significant bump up.

I'm working on the video now. We see Venus above the dawn and a really nice Earth's shadow. After I post the video, I can send out copies of the entire video. It's just under 1 GB as a ASF file and less than 400 MBs as a VWM. I'm trying to convert it to a new format.
My next attempt try to the balloon tp burst before the sunrises. I want to see dawn at a higher altitude.

I wonder if the air pressure drops because the balloon is floating (not held down). When the balloon is held down, there's aa additional force on the balloon. I wonder if that second force shows up as increased pressure.

Or have the outside port just inside the payload. the pressure in there
has to be the same as outside. Or at least every payload we have ever
flown easily would have equal pressure.

If you attended GPSL 2010, I presented a similar graph representing balloon pressure, and this graph also represents the pressure curve presented by the University of Minnesota students. It is great to see a graph with calibrated values! My numbers were relative, but not calibrated.

What size balloon were you flying? My results that were similar to these were from a 1200 gr balloon. I found the 600 gr balloon may not share this same characteristics.

I fly the transducer inside my payload, sealed fairly well from the slip stream via a crushed sponge seal between the payload container halves. It works very well to give you ambient pressure as a reference. (I too am a pilot and know aircraft static and pitot tube systems though quite probably not as much as Mike).

I followed the email string back and see you were flying a 1000 gr
balloon. Your results are similar to the 1200 gr balloon.

When / if I am able to recover the 600 gr pressure data from two flights
ago, I will post it. It will be calibrated, though possibly still a bit
course in A/D quantization.

8887. Re: [GPSL] Internal Balloon Temp and Pressure during flight

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-15 15:53:18 UTC
From: Jerry Gable
Topic: 8880 Message: 8887

I tend to agree with Mike that this is probably caused by turbulence below the balloon. I'm not sure that the outside tube being in the package would have made much difference if it is drag/turbulence induced as the package will be in that zone. As Mike said, it may take getting the static tube out of the influence of the balloon and that would be twisted shut unless it was a ridged tube.

Something for future flights.

Subject: Re: [GPSL] Internal Balloon Temp and Pressure during flight

I wonder if the air pressure drops because the balloon is floating (not held down). When the balloon is held down, there's aa additional force on the balloon. I wonder if that second force shows up as increased pressure.

Slightly off-topic, but Michael, Jon and I spent about 45 minutes scouring the predicted touch-down zone by air last week, and didn't see anything but freshly plowed fields.

Even with the grass starting to brown up, from 500-1000' it's going to be very tough to see the parachute. Note, there's a 700' tower in the middle of that area. :-)

One promising bit of news is that there's lot of hunting grounds up there, and we saw a couple of groups out hunting. Maybe you'll get lucky and one of them will stumble on to it.

Sorry,

Zack, I appreciate the time you took to scour the area. It would have
been great to find that payload, but the where-abouts could be just
about anywhere based on the final flight paths of several of the other
flights that landed in the area that day. It might even be plowed under
by now! I will keep holding out hopes for a call one day.

Thanks for taking the time and expense to look for it, it would have
been great to see it again!

Thank you!

8890. Results of Last Near Space Mission

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-15 22:38:39 UTC
From: L. Paul Verhage
Topic: 8890 Message: 8890

Insead of completing homework, I processed all the data from the last flight. On my webpage is a report that includes data, position reports, and a video.

http://nearsys.com/arhab/flightdata/2010/h/index.htm

The cosmic ray flux was interesting, as was the relative humidity data. The video contains clips up to 113,000 feet where the balloon burst.

I would be interested in attempting another two night flights. One around midnight to see hw the temperature profile chanes without the sun and another to reach 100,000 feet 40 minutes before sunrise.

Well, during ascent, the air inside the payload package is being vented,
since I doubt any that we fly could hold 14 PSI! So there must be a
higher pressure inside in order to push that flow thru whatever leaks
are available. The tighter the box, the greater the internal pressure
required to make that flow go.

And many of these stories are prime examples of extraordinarily sloppy reporting. They are often a story about a story about a story about a launch and the last iteration is so far removed from what actually happened there is almost no resemblance. The journalists (and I use the term loosely) need to go back much closer to the source rather than spending 20 minutes summarizing (badly) what they found with Google News.

Most sci/tech stories in the "big" media seem to suffer from this.

From: L. Paul Verhage
Topic: 8728 Message: 8897

One of the victims of Saturday's near space flight was my SPOT tracker. Again, it didn't produce an output every ten minutes. Upon landing, the wind dragged the capsules through the mud and opened a hatch, spilling the contents. We didn't see the SPOT tracker.

Just a few minutes ago, it radioed in it's position. Here's the link.

http://fms.ws/3rA_V/39.16212/\-94.01965<http://fms.ws/3rA_V/39.16212//-94.01965>

It's two days late, but at least we'll get it back now (probably muddy to boot). Andy lives closest, so he is planning to get it.

And yet when youre in the shadow of a giant statewide university system,
you can't get coverage at all. he he he..

I had one coverage last year, but the only reason that even happened is
because the head engineer of the station is a member of our balloon group!

Andy just emailed that he found it. I wonder if he caused it to transmit.

Well, now to find out why it isn't transmitting every 10 minutes. I'l start withi a check on my service. The first flight transmitted every 10 minutes, so I suspect we're alright there.

We reovered the near spacecraft to the east of that road. Either it landed
on that road and was dragged through the mud (which did happen, I just don't
know if it was that far), or Andy caused it to transmit a position.

That is interesting that it is just now reporting. Saturday I drove half way down that road till it started to get to muddy and didn't go any further. I did go east and west of that point and got nothing. When I was leaving there were two carloads of young people that walked south on that road toward the levy. Mike

Yes even the reporters I spoke to directly could not get it right. We never said we got into space or even close. The 23 miles up was a misquote I said the plane "flew" from release to landing for 23km. I am 46 not 42 and my girlfriend was suppressed to learn I was married.

It was only ever intended as a bit of fun although the construction and tracking was serious.

My intention was to promote ballooning and amateur radio.

We had no idea it would get the attention it did. If it's got anyone to join a proper balloon group then good. If it's upset anyone then I apologise it was not the intention.

But hopefully out of it I will get the chance to do a scientific launch.

I agree with the article linked to

I don't think anybody begrudges the coverage given to you, but many of us wish it was of a higher quality. There's a great story to be told, but it should be told well and factually by the media.

The guy is right - especially for those of us who've been afflicted with balloonacy for, yea, 2 decades or so. But OTOH, it's nice that SOME of us do get some press! It'd be nice if some of those blogs and articles would do a bit of research into the field (what we used to know as "journalism") and put these "novel" events in perspective.

WHAT journalists?? You mean the sci/tech bloggers? They're NOT
journalists - at best, they're mostly online op ed self-publishers.

Hi Steve,

Your work with the PARIS group is excellent - it's not every maiden balloon flight that gets documented so well and recovered so quickly and with such good imagery. I doubt that many of us on ARHAB would gripe about getting even a fraction of the press that El Reg gave ya.

But the point of the grousing is that many of these flights are being covered as if they were equivalent to the landing of the Eagle on the moon!

And there may just a smattering of sour grapes amongst us olde fahrts :=P.

From: Mark Caviezel
Topic: 8911 Message: 8911

Guys:
One guy who gets consistently excellent media coverage is Jonathan Trappe, the cluster balloon guy. His 'secret' is to be very pro-active about it, he generates press release hand outs, photography, and fact sheets and hands it over to all interested journalists. The result: positive and largely factually accurate reporting about his cluster balloon flights.

He gets more astonished and ignorant questions about legality, ATC, and motivation than all of the ARHAB guys.

He is making a flight this week in Mexico that I suspect will create a lot of media interest.

best

- Mark

Mike....The journalists' bottom line is how to do a twist on the story that sells. If they have a choice between covering the following two examples from Colorado:

- EOSS launches student experiments to sample the atmosphere.

- Boy may be trapped inside runaway balloon.

Guess which one gets the journalist's attention and grabs the public's attention.

- Bill WB8ELK

Hi Steve,
Your work with the PARIS group is excellent - it's not every maiden
alloon flight that gets documented so well and recovered so quickly
nd with such good imagery. I doubt that many of us on ARHAB would
ripe about getting even a fraction of the press that El Reg gave ya.
But the point of the grousing is that many of these flights are being
overed as if they were equivalent to the landing of the Eagle on the
oon!
And there may just a smattering of sour grapes amongst us olde fahrts :=P.

Yes even the reporters I spoke to directly could not get it right. We never said we got into space or even close. The 23 miles up was a misquote I said the plane “flew” from release to landing for 23km. I am 46 not 42 and my girlfriend was suppressed to learn I was married.

It was only ever intended as a bit of fun although the construction and tracking was serious.

My intention was to promote ballooning and amateur radio.

We had no idea it would get the attention it did. If it’s got anyone to join a proper balloon group then good. If it’s upset anyone then I apologise it was not the intention.

But hopefully out of it I will get the chance to do a scientific launch.

I agree with the article linked to

Steve

I suppose some jounalists are too busy to research the matter.

If they did, they'd realize there's still alot of neat stuff going on ourt here.

It is written, "If it bleeds, it leads".

Our local NPR station solicited for stories of local interest for it
daily news program. I invited them to join us for a launch and recovery,
describing the roar of the Helium and smell of the crowd - I mean - latex.
Plus the radio traffic and chatter of the students at the recovery site.
They passed, but DID cover a gallery opening at the Art Museum ... by radio.
Go figger.

Well some of what I hoped would happen has, a group of Australians are going to try and also a group of Iranian students.

I do hope they fly a bit of science also.

For those interested the cad files for plane contraction are here http://www.theregister.co.uk/2010/11/17/vulture_cad/page2.html

I don't think getting news coverage is totally the fault of the Journalists they are selling stories. (The inaccuracies are though) and need to write things that will grab the attention of the reader.

According to a piece in the Telegraph a lot of people try to get the pics http://www.telegraph.co.uk/science/space/8127418/Telegraph-captures-pictures-of-space.-Well-Clapham.html

A joke piece obviously.

As for if it bleeds it leads is true. Once sat on a broken down bus I pointed out Jupiter to the chap behind, "so what" was the response. I then said a comet was about to crash into it and the impact would be seen from earth, the force of several nuclear explosions. At which point the whole bus got interested.

I do hope if any of you get contacted by the students you will help out, maybe the following launch they will do some science. But at the very least they will have learnt a bit about the atmosphere.

If any groups in the UK need a hand with a launch I would be happy to help, be it tracking, chasing or making the Tea. Now very hooked on it and want to do another.

Well, one possible beneficial effect of the coverage in the UK may be
prompting an MP or two to inquire why you were compelled to haul the
Limey-built Vulture out of Old Blighty to fly it - and the answer
may inspire an inquiry into your draconian regulations prohibiting
ham radio aboard unmanned weather balloons. I mean, if it's OK
with the Ayatollah, then it oughta please the Queen as well :=).

Hope reigns eternal, eh?

8916. RE: [GPSL] Near Space Is Not Space

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-17 23:36:56 UTC
From: Steve D
Topic: 8895 Message: 8916

Well I have not looked up the reason for it, but I suspect it might have something to do with the pirate radio of the 60's.
On a mission now, there are a couple of BBC radio DJ's that started out in pirate radio, so will start there.
This is going off topic I think so if anyone wants to help or send me info on getting Amateur Radio OK for flight in the UK contact me off list.

Well, one possible beneficial effect of the coverage in the UK may be prompting an MP or two to inquire why you were compelled to haul the Limey-built Vulture out of Old Blighty to fly it - and the answer may inspire an inquiry into your draconian regulations prohibiting ham radio aboard unmanned weather balloons. I mean, if it's OK with the Ayatollah, then it oughta please the Queen as well :=).

Hope reigns eternal, eh?

Hi Steve,

It's illegal almost anywhere in the world for a passenger on a commercial airline flight to key up a transmitter, including a cell phone, while the bird's in flight. You know the caveats that the stewies recite when taxiing out from the gate. The rationale is that those xmitters can QRM the nav radios, like VOR, TACAN and GPS - and we in ARHAB have had to deal with that as well.

However, extending that restriction to ANYTHING that soars over 700 ft above the earth is clearly over-reaching. In the US, and probably anywhere else in the world that has the equivalent of our FAA and FCC, there are exceptions for transmitters that are under control of the pilot in command or the unmanned aircraft operator. If they choose to foul their own nest electro-magnetically, then don't nanny-state them. There may very well be such an exemption in the UK rules, but it would not surprise me that most of the bureaucrats charged with enforcing those regs are familiar with them. We've certainly found FAA folks who have no clue about our FAR 101 regs.

So maybe a good start might be a search for that exemption in the UK regs, and to recite it loudly and repetitively until someone who counts pays attention.

Steve, I was surprised it turned out to be legal in Spain and not the UK as my reading of the regs. suggested airborne operation of amateur radio equipment was not allowed in all CEPT countries.
For UK HAB we have been using low power licence exempt modules - specifically those ones where airborne operation is allowed. We have managed to get a few hundred miles out of 10mW modules so far.

Well I have not looked up the reason for it, but I suspect it might have something to do with the pirate radio of the 60's.
On a mission now, there are a couple of BBC radio DJ's that started out in pirate radio, so will start there.
This is going off topic I think so if anyone wants to help or send me info on getting Amateur Radio OK for flight in the UK contact me off list.

Well, one possible beneficial effect of the coverage in the UK may be prompting an MP or two to inquire why you were compelled to haul the Limey-built Vulture out of Old Blighty to fly it - and the answer may inspire an inquiry into your draconian regulations prohibiting ham radio aboard unmanned weather balloons. I mean, if it's OK with the Ayatollah, then it oughta please the Queen as well :=).

Hope reigns eternal, eh?

On 11/17/2010 15:54, Steve D wrote:

Well some of what I hoped would happen has, a group of Australians are going
to try and also a group of Iranian students.

I do hope they fly a bit of science also.

For those interested the cad files for plane contraction are here
http://www.theregister.co.uk/2010/11/17/vulture_cad/page2.html

I don't think getting news coverage is totally the fault of the Journalists
they are selling stories. (The inaccuracies are though) and need to write things that will grab the attention of the reader.

According to a piece in the Telegraph a lot of people try to get the pics

http://www.telegraph.co.uk/science/space/8127418/Telegraph-captures-pictures-of-space.-Well-Clapham.html

A joke piece obviously.

As for if it bleeds it leads is true. Once sat on a broken down bus I pointed
out Jupiter to the chap behind, "so what" was the response. I then said a comet was about to crash into it and the impact would be seen from earth, the
force of several nuclear explosions. At which point the whole bus got interested.

I do hope if any of you get contacted by the students you will help out, maybe
the following launch they will do some science. But at the very least they will have learnt a bit about the atmosphere.

If any groups in the UK need a hand with a launch I would be happy to help, be

it tracking, chasing or making the Tea. Now very hooked on it and want to
do
another.

It is written, "If it bleeds, it leads".

Our local NPR station solicited for stories of local interest for it
daily news program. I invited them to join us for a launch and recovery,
describing the roar of the Helium and smell of the crowd - I mean - latex.
Plus the radio traffic and chatter of the students at the recovery site.
They passed, but DID cover a gallery opening at the Art Museum ... by
radio.
Go figger.

 Hi Steve,

Your work with the PARIS group is excellent - it's not every maiden balloon flight that gets documented so well and recovered so quickly and with such good imagery. I doubt that many of us on ARHAB would gripe about getting even a fraction of the press that El Reg gave ya.

But the point of the grousing is that many of these flights are being covered as if they were equivalent to the landing of the Eagle on the moon!

And there may just a smattering of sour grapes amongst us olde fahrts :=P.

On 11/16/2010 13:38, Steve D wrote:

Yes even the reporters I spoke to directly could not get it right. We never
said we got into space or even close. The 23 miles up was a misquote I said
the plane "flew" from release to landing for 23km. I am 46 not 42 and my
girlfriend was suppressed to learn I was married.

It was only ever intended as a bit of fun although the construction and tracking was serious.

My intention was to promote ballooning and amateur radio.

We had no idea it would get the attention it did. If it's got anyone to join a
proper balloon group then good. If it's upset anyone then I apologise it was
not the intention.

But hopefully out of it I will get the chance to do a scientific launch.

I agree with the article linked to

I took a quick peek. I use to live in California and saw familar towns.

So it l;ooks like the chase team is going to have to take I-80 across Donner Summit and then down highway 95 south. It's tough to chase east across Califonia's Serria Nevadas.

If they even bother chasing. when will it punch through what ever is keeping it from rising? and if it doesn't will it then come down at sunset, this could be interesting.

Pete Sais had a flight like this in 1999(?) It took seven hours to land.

The winds were 63 MPH when I looked. I wonder if the positive lift is so
low it can't get through.

Does this mean there's significant wind shear across the height of the
balloon?

I guess my task for next year is to make a commerically viable flight
termination unit kit.

What altitude was it at when it levelled off last time? or at least
slowed way down remember it brought up the pressure thing and all that?

And i wonder what is happenening at this level that stopping it from
punching through.

I've already posted in the records page the highest altitude for the flight. Are you the only one watching ..... I don't think so.

This is where solar would come in handy.

I've run a TT3 payload (on the ground) for 22 hours with once per minute
updates.

8933. RE: [GPSL] Near Space Is Not Space

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-18 16:34:11 UTC
From: Steve D
Topic: 8895 Message: 8933

Well some good news is a local primary school got some belated attention of the back of PARIS

http://www.thisissouthdevon.co.uk/news/Pupils-moon-space-spud/article-2908353-detail/article.html

Sadly the reporter failed in the altitude conversion. So I contacted him, they flight made 35km which puts them around 26th on the ARHAB record list.

So a bunch of young children have hopefully been encouraged to do some more science

Steve

Subject: Re: [GPSL] Near Space Is Not Space

Mike....The journalists' bottom line is how to do a twist on the story that sells. If they have a choice between covering the following two examples from Colorado:

- EOSS launches student experiments to sample the atmosphere.

- Boy may be trapped inside runaway balloon.

Guess which one gets the journalist's attention and grabs the public's attention.

- Bill WB8ELK

Hi Steve,

Your work with the PARIS group is excellent - it's not every maiden balloon flight that gets documented so well and recovered so quickly and with such good imagery. I doubt that many of us on ARHAB would

gripe about getting even a fraction of the press that El Reg gave ya.

But the point of the grousing is that many of these flights are being covered as if they were equivalent to the landing of the Eagle on the moon!

And there may just a smattering of sour grapes amongst us olde fahrts :=P.

The question was NOT what altitude did it get to..

The question WAS, what altitude did the slowing and almost levelling
off happen at last time?

I am watching as Lynn says, I try to watch as many as I can, currently willing the balloon to start going up again.

Negative. I'm watching, and I believe G6UIM is also monitoring from England. I just haven't had anything to add to your analysis. I'm holding my breath right now to see if it gets back above 114K which it did earlier (something like 114,403). 113,999 right now!

Lynn (D) - KJ4ERJ - Watching from Palm Bay, FL while working...

Do you have a phone number on the capsule?

We should notify hams to keep an eye out for the near spacecraft. Someone
in Nevada (Utah??) may be able to recover the payload when it comes down.

Joe,

Back when we were first speculating on this flight we guessed 50% lift at 110K feet and 0 lift at 130K feet. I think we were off a little but I think this shows the internal pressure does limit the altitude.

Here is the thread http://groups.yahoo.com/group/GPSL/message/8443

The question was NOT what altitude did it get to..

The question WAS, what altitude did the slowing and almost levelling off happen at last time?

So without enough extra pressure, the helium inside the balloon can't cause
the latex to stretch any further?

Can we figure out a safe minimum lift for the balloon?

8942. Re: [GPSL] Re: [Balloon_Sked] Re: CNSP high altitude attempt on November 18, 2010 at 2:30 a.m. PST.

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-18 17:03:53 UTC
From: Michael Willett
Topic: 8922 Message: 8942
Attachments: 1 described; binary payloads are missing from this source WARC

Exactly. The latex mechanical maximum, the point that the latex is starting to be incapable of further expansion will result in a slight compression of the helium, possibly reaching equilibrium. This is what I explained at GPSL this year with the sudden increase in pressure just before burst. This has been verified by a few of us by monitoring the envelope pressure. I think this holds true with all balloons of this type though it is harder to observe, such as with the smaller 600 gr balloons.

We use to think that using less helium to start with gave the balloon more
room to exapnd and let it reach a high altitude.

Does this mean that the balloon has reached it max altitude, even if it had
a little extra helium inside?

Paul

1900Z should be an interesting time to watch if it' still up then.
right then should be about max heating from the sun. after that it will
start to loose some of the heating and see if it starts to slowly lower
or not.

It's must be running into something that is stopping it. different
temp, wind shear, something. it shouldn't be at the limit of
stretching again yet.

Less helium will allow the balloon to rise farther up to a point. At some point the delta pressure on the balloon reduces the lift because the helium is slightly denser from pressure than the air around it. This happens around 100K feet from what I have seen.

As for the increase in pressure at the maximum stretch, that makes it worse but at some point even the pressure before this point starts to affect lift.

I want to put together something that allows this to be more easily predicted but I haven't had the time or data yet to do it. Since my cruise (Carnival Splender) has now been canceled maybe I can work on this some next week.

Subject: Re: [GPSL] Re: [Balloon_Sked] Re: CNSP high altitude attempt on November 18, 2010 at 2:30 a.m. PST.

We use to think that using less helium to start with gave the balloon more room to exapnd and let it reach a high altitude.

Does this mean that the balloon has reached it max altitude, even if it had a little extra helium inside?

Paul

On Thu, Nov 18, 2010 at 11:03 AM, Michael Willett <mw@...> wrote:

Exactly. The latex mechanical maximum, the point that the latex is starting to be incapable of further expansion will result in a slight compression of the helium, possibly reaching equilibrium. This is what I explained at GPSL this year with the sudden increase in pressure just before burst. This has been verified by a few of us by monitoring the envelope pressure. I think this holds true with all balloons of this type though it is harder to observe, such as with the smaller 600 gr balloons.

One thing you have to account for is that you'll hit the same air density at a lower altitude this time of year. Colder denser air and all that.

I think you'll hit a fundamental limit which will be most closely related to air density. An identical setup will reach a higher GPS-indicated altitude in the summer than it will in the winter. The best altitudes will likely be reached when launched into a stout vertically-stacked high pressure area in the summer.

I'm also tracking and wonder if the balloon will stay aloft long enough to make western Colorado (5 hours). If so, I would hope it stays up another 3+ hours to make it to I-25 and the front range where there is a chance of recovery versus landing in the Rocky Mountains.

I think that the various pressure increase measurements that Michael, Jerry, the Minnesota students, and others have obtained, it is safe to say that the latex response to stretching is not linear. It seems reasonable that the small amount of helium in the balloon cannot supply the required force to stretch the balloon to the breaking point.
The initial helium gas fill was about 120 cubic feet and the burst volume for the 3000 gram balloon is almost 41,000 cubic feet. Using the ideal gas law, the force per square centimeter at burst volume would only be 0.03 Newtons.
I'll try to revisit the breaking force data that my students looked at earlier in the fall, but I think that the required force was bigger than 0.03 Newtons.

So without enough extra pressure, the helium inside the balloon can't cause the latex to stretch any further?

Can we figure out a safe minimum lift for the balloon?

On Thu, Nov 18, 2010 at 10:44 AM, Jerry Gable <jerrygable@...> wrote:

Joe,

Back when we were first speculating on this flight we guessed 50% lift at 110K feet and 0 lift at 130K feet. I think we were off a little but I think this shows the internal pressure does limit the altitude.

I think that the various pressure increase measurements that Michael, Jerry, the Minnesota students, and others have obtained, it is safe to say that the latex response to stretching is not linear. It seems reasonable that the small amount of helium in the balloon cannot supply the required force to stretch the balloon to the breaking point.

The initial helium gas fill was about 120 cubic feet and the burst volume for the 3000 gram balloon is almost 41,000 cubic feet. Using the ideal gas law, the force per square centimeter at burst volume would only be 0.03 Newtons.

I'll try to revisit the breaking force data that my students looked at earlier in the fall, but I think that the required force was bigger than 0.03 Newtons.

Howard

So without enough extra pressure, the helium inside the balloon can't cause the latex to stretch any further?

Can we figure out a safe minimum lift for the balloon?

On Thu, Nov 18, 2010 at 10:44 AM, Jerry Gable <jerrygable@yahoo.com> wrote:

Joe,

Back when we were first speculating on this flight we guessed 50% lift at 110K feet and 0 lift at 130K feet. I think we were off a little but I think this shows the internal pressure does limit the altitude.

The question was NOT what altitude did it get to..

The question WAS, what altitude did the slowing and almost levelling off happen at last time?

1 N = 0.2248 pounds.

We'll need to know over how much area the 0.03N is applied.

96 MPH at 115K feet! That balloon is cooking right along!

I guess now you start to think that actually, the balloon is going slower than the earth is spinning!

In my note, I said 0.03 Newtons per square centimeter. (I've been back in the lab with my students.)
Our students found the breaking force for small strips (approximately 2 cm wide and 15 cm relaxed length) of latex balloon earlier this fall to be between 5 and 12 Newtons.

On 11/18/2010 11:45 AM, BASE wrote:

I think that the various pressure increase
measurements that Michael, Jerry, the Minnesota
students, and others have obtained, it is safe to say
that the latex response to stretching is not linear.
 It seems reasonable that the small amount of helium
in the balloon cannot supply the required force to
stretch the balloon to the breaking point.

The initial helium gas fill was about 120 cubic
feet and the burst volume for the 3000 gram balloon is
almost 41,000 cubic feet. Using the ideal gas law,
the force per square centimeter at burst volume would
only be 0.03 Newtons.

I'll try to revisit the breaking force data that my
students looked at earlier in the fall, but I think
that the required force was bigger than 0.03 Newtons.

So without enough extra pressure,
the helium inside the balloon can't cause
the latex to stretch any further?

Can we figure out a safe minimum lift for
the balloon?

The question was NOT what altitude
did it get to..

The question WAS, what altitude did
the slowing and almost levelling off
happen at last time?

http://swns.com/spudnik-amazing-pictures-from-potato-launched-into-space-181430.html

Pupils at Landscove CofE Primary School dressed the spud with a white beard and red bobble hat before positioning him into a ‘shuttle’ made out of a two-litre plastic drink bottle.

The ‘spacechip’ – named Spudnik2 – was then tied to a helium weather balloon with a camera attached and launched from the local village car park in Devon.

They watched as it soared 17 miles up – reaching 90,000ft – before the balloon to burst and the shuttle floated back down to earth on a parachute and landed 140 miles away in Hampshire.

The KU flight last week used a 3000g balloon with 15 pounds of lift (10 pound payload). The balloon slowed down the last 8 minutes of flight. So even with lots of lift, it looks like the balloon experienced difficulty expanding near the end of its flight.

I'm a little disappointed, I was hoping for a Nebraska recovery with
headlines...
CNNSP recovers CNSP.

From: gregwilliams@knology.net
Topic: 8922 Message: 8968

Somebody might want to get on the horn with some Utah hams pronto. I don't see many stations in Utah at all on APRS. It's actually being reported by stations in Colorado.

Looks to be landing near Hwy 257, just west of I-15. Elevation in that area is 5000' so the Colorado digis may keep it tracked until the last couple of thousand feet.

Greg, K4HSM

8969. RE: [GPSL] Spudnik a success

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-18 19:51:34 UTC
From: Steve D
Topic: 8962 Message: 8969

Well I will email and see if I can get a story for them. Something like high altitude balloon enthusiasts worldwide were impressed etc. and are offering equipment for another launch. unless someone else wants to write something up.

These are keystage 2 children so aged 7 to 11. unless someone else wants to write something up.

The 90,000ft is incorrect according to the journalist who wrote the original piece they made 35km or around 115,000ft.

Comments are allowed on the original link I posted.

The school can be contacted on admin@...

That's very nice of you to offer them equipment Paul.

http://swns.com/spudnik-amazing-pictures-from-potato-launched-into-space-181430.html

Pupils at Landscove CofE Primary School dressed the spud with a white beard and red bobble hat before positioning him into a 'shuttle' made out of a two-litre plastic drink bottle.

The 'spacechip' - named Spudnik2 - was then tied to a helium weather balloon with a camera attached and launched from the local village car park in Devon.

They watched as it soared 17 miles up - reaching 90,000ft - before the balloon to burst and the shuttle floated back down to earth on a parachute

and landed 140 miles away in Hampshire.

I'm thinking this will land not far from I-15 in the Meadow UT area. There is a digi on the ridgeline to the east of Meadow that should pick it up fine all the way to the ground. If it lands before it gets to the forested area east of I-15, recovery should be almost trivial.

Hi Paul,

I guess they will need a balloon. Lol.

If they are interested, if you want to ship to me I will see if I can get some news coverage of the hand over of equipment on your or anyone else that donates behalf.

I don't particularly need coverage for myself. Lol. Up to you on that.

Make sure you label it a donation else customs will charge the recipient.

My address is correct on QRZ

here ya go, it asks about someone trying it, but i guess I beat them.

Attached are the two Bill & bikini Files.

Hey dudes! the hackers say they have fixed this, anyone have some time to try it out? this is what they say to do to make any video play in these canon Cameras. Problem the way to do it is in Russian. Anyone?

All this stuff has been examined a long time ago and everything works.
Here is the link to description in russian, maybe google translate can help you with this.
http://chdk.clan.su/load/2-1-0-2
In any way there are a lots of pictures so it should be easy enough to understand.

In short: you will need to convert your video using VirtualDub with fallowing parameters - mjpeg codec (subsampling 4:2:2), 15 fps, resolutions 320x240/160x120/640x480.
Then save as AVI from VirtualDub and use this tool to create THM preview -
http://chdk.clan.su/load/0-0-0-2-20

PS: Before editing video in VirtualDub you should install MJPEG codec (http://download.accusoft.com/picvideo/PICVIDEO.EXE), you can find registration data in the archive below with test video.

Here is converted sample movie, try will it play or not.
Codec serial number included as a bonus

Thanks Joe, I didn’t miss the thread, looks like you changed the subject.
My SD1000 takes AVI, but my SX200 takes MOV movies.
Don’t understand why Canon decided on the MOV format.

Well, yeah, sorta. But it's still moving with the Earth relative to the sun line. The circumference of the the Earth is Pi x 8000 mi, or about 25,000 miles, so the equator is moving about 1000 mph relative to the sun line. At 40d N lat, apply cos(40d) and get about 800 mph.

Thats an awful large window. The strong is more than twice as strong as
the weakest test? We used a tensile strength machine, and ran a dozen
test samples, and the high was 17.2 Mpa and the Low was 16.2 Mpa the
average came to be 16.7 Mpa Tensile Strength.

Joe,
It was a very simple first run of a test with a generic force transducer. The balloon strip was tied to the hook on the end of the transducer and a student pulled down on the strip until it broke. Some of the scatter is due to the simple set-up.
I would not get excited about the number, but just the order of magnitude. The force at break was around 10 Newtons. Of course, you are quoting tensile strength value. Our answers would have a larger scatter, but come in between 10 and 24 Mpa.
If we took greater care, I imagine that we would get more consistent values, but we certainly agree with your numbers.
Howard

So without enough extra
pressure, the helium inside
the balloon can't cause
the latex to stretch any
further?

Can we figure out a safe
minimum lift for the balloon?

Topic: 8922 Message: 8984

I understand,

Plus those numbers are probably a tad low too, because of any edge defects in the cut sample will cause it to tear prematurely true?

Our test machine uses a special Die and press machine to cut the test samples out of the raw material, and of course any microscopic nicks or same would cause a similar defect in the cut and Like a glass cutting cause it to fail at this defect.

The machine uses self gripping clamps where it automatically grips the ends of the test sample and automatically adjusts for even loading etc.

It was at a plastic company I used to work for that had the machine. it cost them $380,000 bucks!

8985. Landscove School

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-19 16:07:53 UTC
From: L. Paul Verhage
Topic: 8985 Message: 8985

I've contacted Landscove and will send them a BalloonSat Mini and Temperature Array for their next launch.

I've mentioned before that I plan to start a BalloonSats without Borders program that will send a BalloonSat around the world to hams with near space experience. I have a BalloonSat design in mind and will start it after I complete my comps next semester. I imagine running a program like this would look good on my vita.

Steve came up with a follow-on idea of sending a curriculum to other countries. It would include balloons, parachutes, tracking equipment, helium, and a BalloonSat students would build. It's a much more expensive program than B w/o B, but could have a great impact on education.

We're wondering how you could pay for something like this. Any suggestions for donors etc, would be appreciated.

I think it would be great to have a kit that schools could assemble even if they have to put some money towards it. Primary schools in this country don't have a lot of money. But the ability to fly a balloon with a science payload would be a great educational experience.

I do have one potential sponsor, I will get in touch with them and see what they are prepared to do.

I think a webpage explaining the idea so that sponsors and schools can get an idea of whats happening would be a good start.

If you are looking for balloons for this, someone has a bunch of 600G balloons (more than 10) on ebay for $20 each. I bought a couple and they are in good shape, still beige at least.

Wow, where did this flight come from?

What r they using etc.?

This broke records already 130006 right now at 1700 Z

Not sure as to when the river will freeze over there so maybe it hit thin ice but looking at the area maybe it was recovered before it had tyme to sink .

I have been on the phone with a ham in the area he is hearing a signal on 144.390 so it must be out of the water it's last transmission location is less than two miles from his qth

That's cool.

I'd like to know what they flew for a flight train.

Payload. amount of lift, the balloon etc.

DFing on 144.39 is horrid. unless youre using a doppler system.

First the transmission is soo short it's tough to get a peak on it.
Plus with all the dozens of other signals all running it's rard to know
which one is the right one.

Thats where the ultra LOUD alarms come in handy. like the ones we use if
your withinn like a mile you can hear it.

I searched a few ago on the aprs.fi site for zip code 04239 and the only thing running on that site any where close to that zip is the balloon. There are only 8 hams in that zip code so not many around to be doing much.when it's found the ham I spoke too will shoot me an e-mail i also gave him what info i had on the balloon which is not much. But I have sparked a interest in a older ham who has not been away from HF in a long tyme....

I searched a few ago on the aprs.fi site for zip code 04239 and the only
thing running on that site any where close to that zip is the balloon.
There are only 8 hams in that zip code so not many around to be doing
much.when it's found the ham I spoke too will shoot me an e-mail i also gave
him what info i had on the balloon which is not much. But I have sparked a
interest in a older ham who has not been away from HF in a long tyme....

DFing on 144.39 is horrid. unless youre using a doppler system.

First the transmission is soo short it's tough to get a peak on it. Plus with all the dozens of other signals all running it's rard to know which one is the right one.

Thats where the ultra LOUD alarms come in handy. like the ones we use if your withinn like a mile you can hear it.

I just made a phone call to the ham that lives like 3 miles south of there he went out looking for it it is still sounding on 144.390 but it's not in the cornfield under where the last known signal seen heard on aprs.fi he seams to think it may be on the island or on the south side of the river in the lumber mill ......

I see va3zks-9 is closing in on it going the long way around

An independent DF beacon is even better - redundant and DFable.
BTW, sri I missed watching that one - was busy handling traffic
for the Colo statewide SET.

Joe, I agree, I have tried to get flight information from high altitude record holders with no luck. Oh well we've learned how to build pretty good floaters.

9011. RDF Beacon for HAB Use

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-21 01:56:23 UTC
From: Pete Lilja
Topic: 9011 Message: 9011

In the thread with the 130,000' flight of today (great job, BTW) there was some talk of a redundant RDF beacon.

We've used the Big Red Bee <http://bigredbee.com/BeeLine.htm> and it's saved us on a couple of flights. These things are small, lighweight, self-contained, frequency agile and they just work. Oh, and they're inexpensive. They utilize the 70cm band so a small handheld Yagi makes it easy to bang around cornfields and thick brush - not to mention much easier to get in and out of the backset of the car. RDF with a ArrowAntenna offset attenuator <http://arrowantennas.com/main/4ofha.html> and you'll dial right in on the Beeline RDF beacon. Oh, and Arrow makes some nice handheld Yagis, too (I have a 5 element 70cm Yagi but the 3 element is much smaller!).

I simply drill a 1/4" hole in the lid of an empty pill bottle and pass the Beeline's SMA connector through and screw on the 7" whip antenna. That pill bottle gets taped to the suspension line for a HAB flight. 17mW of power goes a long way and the LiPo battery lasts a long time and seems to take the cold well enough.

Just about a year ago we lost a HAB's antenna during PBC. We drove around for hours looking in the wrong places. Eventually we heard the RDF beacon after dark and and found the payload after a relatively short RDF session.

The BigRedBee Beeline RDF <http://bigredbee.com/BeeLine.htm> beacon is a terrific back-up. I have no affiliation - just a satisfied user.

9012. White Star Balloon live stream of their benefit concert online now

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-21 02:47:02 UTC
From: wb8elk@aol.com
Topic: 9012 Message: 9012

For those wanting some good entertainment on a Saturday night....the White Star Balloon group has come up with a great way to bring in some funding for their upcoming trans-Atlantic flights....they are holding a benefit concert in their LVL Hackerspace building in Louisville. You will see their 40-foot tall balloon inflated in the camera view.

http://www.ustream.tv/channel/highball-1

or go to www.ustream.tv and search for White Star Balloon.

9013. lost HAB

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-21 17:25:19 UTC
From: Keith Kaiser
Topic: 9013 Message: 9013

Next time David you might want to post your flight with the ARHAB groups by submitting the form on http://arhab.org that way the entire community is aware of your flight. As you can see I've forwarded your note to the three primary balloon groups in hope of helping you locate your balloon.

Good Luck!

On Nov 21, 2010, at 12:24 AM, David Jones wrote:

> My name is David Jones (KF5HUV-11) from Dallas, Texas. On 11/19/2010 a partner and I launched a HAB from Dallas and it landed in South West Arkansas (33.98672 -94.04364 Coordinates sent by spot messenger after touchdown)
>
> The flight went to an altitude of over 100,000 ft. Needless to say, it caught a 65mph NE Jet-stream and the balloon traveled much farther than planned. We took the 5 hour drive to the location, attempted recovery but, we lost too much daylight to proceed. If any of you, know anyone in that area, that could help recover it; we would be very grateful. We are offering a $200.00 reward. More details can be found here.

9015. Flight in January?

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-21 19:00:44 UTC
From: L. Paul Verhage
Topic: 9015 Message: 9015

I have a 600 gram balloon and would be interested in using for my first H2 flight in January.

Would this be something KC and the surrounding area would be interested in?

Pay load found hanging in the full November moon just south of river in Jay Maine at n44 30.70 w70 14.74. 30ft up tree. Celebratory libations preceded a stay at a motel in Wilton. Thankfully the local hardware store was open at 8am on a Sunday morning for supplies and we are having breakfast before heading back to attempt recovery again.

9017. Re: [GPSL] Re: ve3rex-11 - APRS settings

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-22 16:33:08 UTC
From: Michael Willett
Topic: 8988 Message: 9017

I looked at some of the APRS numbers to see what ascent rate was used
and such, and noticed the APRS appears to have been set to smart
beaconing and WIDE1-1,Wide2-1...

Youch! I imagine the APRS network went berserk!

I was impressed that they made that altitude, while in the cold season
with a very respectable payload on board!

Overall, Great luck and Great job!

What was this respectable payload?

How about the balloon?

or anything that flew?

From: Dan Bowen
Topic: 9019 Message: 9019

Hi All,
We had such a great time last Saturday at the White Star fundraising party/concert, with members of the band The Apples in Stereo. Had a few big balloons, lots of science demos, and about 75 people attend. We raised over $700, a big step toward our trans-atlantic flights, it will pay for the balloon envelopes. Enjoy these pics taken by a staff photographer of the local paper:

http://whitestarballoon.com/?p=301

Thanks,
Dan

Thanks,
Dan

The DNS isn't resolving for me on Cox. The domain is still registered
though through late next year.

I'm guessing that the A record somehow got deleted or a server went down
with GoDaddy.

Hi Paul,

"Firefox can't find the server at www.nearsys.com."

Either the server's down or DNS can't find it.

I use Qwest DSL.

9033. Re: [GPSL] NearSys website

Yahoo group: GPSL (2009 — 2010)
Date: 2010-11-28 18:30:45 UTC
From: Zack Clobes
Topic: 9020 Message: 9033

The A record is the "database" entry that converts Nearsys.com into the IP address of their server. If it doesn't exist, then PC's everywhere suddenly become clueless. Mark is right, this is most likely an issue with your web host (apparently GoDaddy) - they should be able to fix it for you.

Sometimes you can see intermittent issues right after a change was made because the Internet browser can cache this, the PC can cache this, corporate servers can cache it, and the ISP's servers can cache it. In other words, sometimes you have to just be patient after the fix is put into place.

You should be able to type 'ping nearsys.com' in at a command prompt, and it should return some IP address and try pinging it. If it doesn't, there's probably a DNS problem. If in doubt, reboot your PC and try again to eliminate most of the potential problems on your end.

Here’s what the spec sheet says about limits...
Operational Limits
Altitude < 18,000m or velocity < 515m/s
(COCOM limit, either may be exceeded but not both)

I bought one of these for HABing. It's hard to beat at $38. I stuck it in a plastic project box from Radio Shack and made a cable to plug in to my OT+ from Argent.

Unfortunately, I have yet to fly mine but Scott from Argent has flown the GPSr in a HAB at least twice. It works.

My understanding is he's developing a small transmitter with TNC using this GPSr.

Hi Paul,

I've flown this one several times .... one night flight was at -40 deg C for several hours and it worked fine.... it did seem to be desensed by my transmitter and I had a couple of dropouts....but it did quickly recover each time.

From: L. Paul Verhage
Topic: 9034 Message: 9040

Okay, that's what I needed to know. Unitraq says the version I have is their high altitude version. It was easy to put it together and test it on the ground. I just wanted to know if it had been tested above 100,000 feet before I bought another.

The price is really nice if I order 10 of them. My plan is to include it with my flight computer kits.

Hi Paul

The data sheet on Scott's web page reads:

"(Note: *Firmware special supports altitude > 25KM with adjusted algorithm for space application, but not for very high dynamic*.
* Not for comerical airplane and land application. If it is used in both cases, large position error may occur due to bad satellite signal.*) "

I'm not sure what their definition of "large" position error is. A ground test, or even better a flight test with a known GPS would probably give you a good idea. It would also give you a great reason to fly!

When I first looked into this receiver, I was concerned they might not have set it up for altitudes of 100,000 feet. But after hearing Bill's account, I'm happy with the receiver and feel confident in ordering more.

I do have one for a test and it works well on the ground. I was hoping to put one up for the ultimate test. However, Bill made that unnecessary.

Joe Murray, KØVTY was kind enough to pass this along to me. Here it is just in case there are any students in the Section who might be interested.

Date: Thu, 25 Nov 2010 10:59:12 +0100
Subject: [amsat-bb] 1st IAA Conference on University Satellites Missions
and Cubesat Conference Sponsorships and Accommodation

Dear all,

we are pleased to announce that ESA has kindly offered ten scholarships for students who will present a paper at the 1st IAA Conference on University Satellites Missions and Cubesat Conference next January. You can find the information at the following link:

ESA scholarships
<
http://www.gaussteam.com/index.php?option=com_content&view=article&id=111&Itemid=214
>

Furthermore, we have reached an agreement with two hotels for the accommodation of the participants. You can find all the information at the following link:

Accommodation
<
http://www.gaussteam.com/index.php?option=com_content&view=article&id=109&Itemid=211
>

We hope that this will encourage students in participating to the Conference.

Best regard

From: L. Paul Verhage
Topic: 9044 Message: 9044

It looks like I'll be launching a weather balloon for teachers at KATS Kamp on Saturday, April 16. The launch site is south of Junction City. I'll have teachers make BalloonSats Friday and track the flight over the internet. I'll be looking for chase crews who can bring the BalloonSats back.

This is just a heads up, I'm not looking for any commentments yet.

Aeronauts,

As you guys all know there is no requirement to list your flights with us on the <http://www.arhab.org/ARHABlaunchannouncements.html> web sit. But when you do the number of participants in any given launch is increased by several hundreds of users on the site.

I must believe that there are upcoming flights but I have none listed. I know EOSS must have some plans, I know Paul has some plans and I bet Bill has plans. Guys, send me the details using this form <http://www.arhab.org/launches/launches/launch.html> so we can tell the world what we do.

Thanks... Keith

Dear friends,
Snow is forecast for Saturday, which means the next flight (number 56) for BASE will be next year. 2010 was a good year with 16 flights and all systems completely recovered. (Special thanks to those that helped on the Scout flights where I stayed in camp.)
I anticipate the first flight in mid to late February 2011. 2011 should include flights with descent on balloon and will also probably have our first hydrogen fills.
Thanks for your support.
Have a Merry Christmas and Happy New Year,Howard, KC9QBN

Hi Keith,

Whenever I've tried to enter a new flight on the arhab.org web site, I can't get past the captcha gate - regardless how I enter the text, it kicks out on a captcha error. I run W2000 & Firefox. However, when I try it on my Mac at work, it works ok with Firefox. Others may have experienced the same problem, which may partially explain the low reporting rate.

Paul,
Personally, I have not yet published anything about high altitude ballooning. I have given oral presentations at different conferences and also had some poster presentations (both mine and from my students). One challenge is to find a suitable journal for any publication. A second issue is the difficulty in obtaining statistically valid data for our experiments. The new effort begun this fall to study electromagnetic showers in lead may lead to a publication, although it could take a few years to get enough data to be confident in our results.
I did a quick search using our Web of Science server through the campus library and it yielded a few results.
These two appear to be potentially relevant.

The high altitude student platform (HASP) for student-built payloads

From: wb8elk@aol.com
Topic: 9050 Message: 9054

Paul,

I'm one of the authors on this paper that was published as part of an IEEE conference proceedings about 10 years ago...topic was using high altitude balloons to characterize solar cells in the stratosphere based on the Wayne State Univ/NASA Glenn Suntracker series of balloons that was launched by Dr. Woodyard KC8MSY from George Flinchbaugh's (WA8HDX SK) farm in Findlay, Ohio that was the site of my first Balloonsat in 1987:

http://ieeexplore.ieee.org/xpl/freeabs_all.jsp?arnumber=916136

A follow up paper at a more recent IEEE conference that included our own David Snyder KB8PVR:

http://ieeexplore.ieee.org/Xplore/login.jsp?url=http%3A%2F%2Fieeexplore.ieee.org%2Fiel5%2F9889%2F31426%2F01488263.pdf%3Farnumber%3D1488263&authDecision=-203

So....a target journal would be the IEEE as well as the AIAA (I was a member of the AIAA Scientific Ballooning advisory board in the early 90's).

Hi Howard,

Thanks for digging that up. Actually, the AirCore sampler was developed by
Dr. Peiter Tans of NOAA in Boulder. EOSS just hauls it up into the
stratosphere and gets to its landing site & closes the valve in short order.

We've done 3 or 4 of these flights for NOAA over the past few years.

The AirCore payload weighs in at almost 7 kg, so it flies non-exempt under
a 3000 gm Totex.

I checked the KU library and Google Scholar. Interestingly enough, there were more articles on Google Scholar. Even still, there's not a lot written. I'm a little suprised.

I'm looking more at publications in education journals. So more along the lines of what pupils get out of the experience is what I'll write about. I plan to run the BalloonSats lab of AE360 like students were building satellites. We'll do simlar tests, flight planning, and data analysis. I'll be learning how to use Matlab to model a mission and its results. The text for the labs will be my BalloonSat articles for the Society of Amateur Scientists. By the end of the semester I'd like to edited the articles enough to publish them in a book.

So I need to look at examples of educational research and see how lab classes were analyzed. The organization for engineering education looks like a good start, as does NARST.

I recently joined the Near Space Network like Howard mentioned, but have not had the time to log in and pay everyone a visit. I guess it's time to do that.

Thanks for the links everyone, I'll get on them. I think one thing this does show is that a program with lots of accomplishment and potential isn't discussed much in educational journals. With luck, I'll get pone passed peer review this summer.

Paul

From: Mike Bogard
Topic: 9057 Message: 9057

Has anyone used a Vivitar DVR 550 Camcorder in there balloon flights? If so how did it work and run time? Thanks Mike KDØFW

9058. White Star Balloon: Speedball 1

Yahoo group: GPSL (2009 — 2010)
Date: 2010-12-14 08:05:22 UTC
From: James Coxon
Topic: 9058 Message: 9058

Dear All,
The White Star Balloon Team are going to attempt to launch their first zero pressure balloon this weekend (18/12/10 - 19/12/10). The main form of communication will be via the onboard satellite modem however they will also be flying a HF transmitter constructed by WB8ELK. This radio transmitter will be tx'ing on 40m and will alternate between RTTY and DominoEX. Potentially the flight will last for a number of days and signal reports will be welcome. The format of the transmitter will be compatible with the dl-fldigi/spacenear.us system where if you can receive the telemetry you run dl-fldigi a modified version of the excellent soundcard software fldigi which will detect the strings, verify and upload them to a server where they will be plotted onto a map at http://spacenear.us/tracker/ . The more people who listen out the better!

The flight details:
* Date: First launch window December 18, 2010
* Time: 6:00AM local time
* Location: SpacePort Indiana, Columbus Municipal Airport, Columbus IN
* Target Float Altitude: 250mb Pressure Altitude (~10350m)

Of course there is still lots to do for the payload etc so there is a chance that the first launch window will be missed.

To get involved with the tracking you'll need an HF radio connected to the sound card on your computer and you'll need to run the dl-fldigi software - see this guide for more info
http://wiki.whitestarballoon.com/doku.php?id=hardware:radio:wb8elkwhitestarn17

The signal should be found at 7.102Mhz USB.

If you are planning to listen out for the balloon flight it would be great if you could send me a quick email to jacoxon@... so that I can judge rough numbers, any problems with the software get in touch.

Disclaimer: While I'm not on the White Star Balloon Team I've volunteered to recruit the HF listeners and coordinate the use of dl-fldigi/spacenear.us

Apologies,
The due to technical issues the balloon launch has been postponed
until after the New Year - I'll start rallying listeners the week
before!

9061. WB8ELK HF balloon test flight on 40m from Huntsville AL Sunday afternoon

Yahoo group: GPSL (2009 — 2010)
Date: 2010-12-18 23:21:26 UTC
From: wb8elk@aol.com
Topic: 9061 Message: 9061

Date: Sunday Dec. 19th at 4:30 pm CDT.

Falkville, AL: 34.4086, -86.8133

7.077 or 7.102 MHz HF telemetry

DominoEX16, 8-bit ASCII RTTY at 110 or 45 baud, Hellscreiber and CW.

Predicted landing zone is southeast of Atlanta.

Streaming video of the launch: www.batc.tv members streams WB8ELK

This is a test of the HF transmitter that will be used for the White Star trans-Atlantic flights in January.

- Bill WB8ELK

A guide to listening out to this flight can be found here:
http://wiki.whitestarballoon.com/doku.php?id=hardware:radio:wb8elkwhitestarn17#listening_information

The flight path will be plotted on http://spacenear.us/tracker (there is another flight earlier today from the Netherlands as well)

Bill what kind of HELL will it be,

Anyone know?

I'm gonna run both dl-dilfigi and Multipsk to decode all the modes.

again as someone else has asked, any pre flight testing we may hear?

9065. WB8ELK HF Balloon on 40 meters today updated info

Yahoo group: GPSL (2009 — 2010)
Date: 2010-12-19 18:33:24 UTC
From: wb8elk@aol.com
Topic: 9065 Message: 9065

Launch is at 4:30 pm CST (2230 UTC)...or in BST (Bill Standard Time) that would be anywhere between 4:30 pm and midnight.

I've finalized on 7.077 MHz.....if you tune it in at 7.077 USB, the audio center will be at 1750 Hz.

modes are: DominoEX16, 110 baud ASCII RTTY, Feld-Hell and CW....the Feld-Hell and CW are only every 5 minutes.

The transmissions start with DominoEX at the top of each minute, followed by the RTTY....the Hellscreiber and CW follow the CW every 5 minutes.

Tracking online at: http://spacenear.us/tracker

If you use the dl-FLdigi program to track, you can set it up to update the SpaceNear website with your reception. James M6JCX posted a good tutorial on where to download the program and how to set it up in an earlier post today.l

Streaming video starting at 4:00 pm CST (2200 UTC) at: http://www.batc.tv Member's Streams then WB8ELK

Hi Bill,

Do you have any preference as to which mode you would like me to capture or would you like me to switch between modes?
I might not be able to sit by the rig for the duration.

Hi Harry,

Whichever mode comes through the best....probably the DominoEX16 if you're not at the rig since it tolerates drifting. I'll be on 7.077 USB....the audio will come in with a center of 1750 Hz.

Nice sequence Rick!

I did venture out and took a few shots. It was 53 deg, but had very dense atmosphere with fog forming. Had to keep the camera covered between shots. It’s the first time I’ve shot the moon with my Canon SX-200. SO I bracketed up to 10 sec with varying ISO from 200 to 800. I didn’t get my 10” reflector scope out because of the fog. I really would’ve liked to have had my old Nikon F film camera out and hooked up to the scope. Digital, even at 12mp & 12 opt zoom sucks. Film is still my choice! I’ll attach a pic here and see if it goes through.

Yep, our skies were close to ideal. There was a super thin layer of cirrus clouds, the kind that leaves a ring around the moon which was evident. I didn't get any photos of that. Too large for the lens I was using and I had all the optics cooled down to ambient and didn't want to go inside and drag out a "hot" lens and heat up the camera a little. Figured everything was equalized to the 18 deg F conditions and didn't want to introduce any variables or foggy pictures into the equation mid eclipse. The haze factor of these ice crystals was extremely low and had a low to no effect on the photos.

I was freezing out there so no video. Course, I took the photos from a tripod, not a telescope mount with tracking capabilities. So, video would have been pretty much impossible without a ton of post processing. I thought it would have been fun to do the video about half way through the event but by then it was WAY too late. Perhaps next time, which looks to be April of 2014 for the US.

I was really hoping to take pictures every 5 seconds and animating it into a movie. Sounds like Nebraska and Colorado had clear shots.

You need to load the "original" size (10K pixels wide) to really see anything.

I used a tripod and timer and as you can see in the one pic there is star movement so no tracking here either. I wasn’t even sure we’d see anything because it was cloudy at midnight and my 10” scope takes at least a couple hours to normalize. I was planning on using CHDK on my SX-200, but decided just to experiment with manual shots this time to get a basis for a future night script.

That sucks, I'm sure someone else is going to create fanastic animated videos of lunar eclipses before then.

I've produced animated movies of clouds by photographing every five seconds and dumping all the images into MS Movie Maker My minimizing each frame and doubling their speed, you get a high definition, sped up movie of changing clouds.

I was trying to find a clock driven telescope mount, but the clouds here made it moot. Perhaps in 3 years I can try again.

9083. Explorer-1

Yahoo group: GPSL (2009 — 2010)
Date: 2010-12-22 21:43:13 UTC
From: Les Roblin
Topic: 9083 Message: 9083

Three Rivers Flight Civil Air Patrol is proud to announce our first ever High Altitude Balloon launch. The name of our package is "Explorer-1" and is listed on ARHAB announcements.

The package/flight train is very simple for our first attempt.
1200 gr. Helium filled balloon
Parachute
Radar Reflector
APRS - Garmin 18x LVC GPS, OpenTracker+, PX-777 2 Meter Transceiver
APRS is on 144.39 MHZ/Wide 2-1 using my call sign K7PTZ-11
300 ohm twin-lead J-pole portable antenna
Vivitar Camera modified for auto shutter with a 1900+ photo capacity
MK111 timer set at a 20 second shutter interval

Launch date will be 15 January 2011 from Cloud Country Airport Grape Creek, TX 31.58233 -100.56001 at 0900 CST (1500 UTC). Alternate date is 22 January. If it is necessary to change dates we will post when and where it will be.

Photos will be posted on our website http://3rcs.webs.com/ <http://3rcs.webs.com/> as soon as we can.

Project Officer

9084. WB8ELK HF balloon payloads have been recovered

Yahoo group: GPSL (2009 — 2010)
Date: 2010-12-23 18:20:02 UTC
From: wb8elk@aol.com
Topic: 9084 Message: 9084

Thanks to all for participating in receiving the 40 meter telemetry from Sunday night's HF balloon flight. I logged reception reports from across Alabama, IA, KC area in MO, IA, WI, TX, MI, OK, IL, Ontario as well as reception via internet radios in OH and CT. Thanks to WD5EAE's beverage antenna in TX (as well as W1TXT's internet radio in CT) we received a final report just 190 meters above the ground. That was the good news. The bad news is that it appeared to have landed smack dab in the middle of an artillery shooting range in Fort Stewart just west of Savannah GA.

Sure enough, personnel at the artillery range called me first thing in the morning and told me they had found the payloads and had them in their command center. Fortunately they didn't sound too upset over it. Tim from our group (his son's science fair experiment was onboard) is planning to travel over there to get the payloads from the base personnel. Good thing that they found it since otherwise our payloads would've been target practice....I'll still check for bullet holes when I get things back. I had attached an empty water bottle on the bottom of the 66 foot long wire dipole to hold it straight...I put some coins and a message inside. That's where they saw my phone number, so a stratospheric message in a bottle works as well as one sent out to sea.

Perhaps we should do a Records category for worst landing spot....the candidates for the top 5 so far
(any other suggestions?)

1 - O'Hare International Airport
2 - Nuclear Power plant in IL
3 - Army Artillery shooting range in SC
4 - car windshield on highway in KS

5 - on top of large truck on highway in IN

Honorable mention: 6 - Alligator infested swamp

This test was running only the exciter for the upcoming Trans-Atlantic flight attempts in January.....Sunday's flight was only running about a quarter watt on 40 meters. The Inventek GPS as well as the Multi-Mode tracker operated for hours at -45 deg C so this was a really good cold test of the system. It was all powered by 4 lithium AA Eveready batteries.

The DominoEX well outperformed the RTTY when it got weak....and I received a few nice reports from the Hellscreiber as well.

The combination of dl-FLdigi with it's automatic plotting to the http://spacenear.us/tracker website worked very well and should give us a great way to track the upcoming trans-Atlantic flights,

73s de Bill WB8ELK

Bill,

Any idea when MMT boards will be available for sale? I'm finally considering getting off my *** and taking the General test soon so I can fly HF.

NSTAR managed to straddle two phases of a 30 kV feed with a J-pole antenna and feedline in 2001.

Well, the thanks go to you Bill ..!.. You always find projects like this
to keep us up late and well-entertained. Live video and telemetry ..
Who could ask for much more. AND, it was a good functional test as well.
Be sure to let us know about your next flight (and if possible - give me
more than a 24 hr heads-up, maybe I can help get to launch on time..)..

I've posted a quick piece on this flight : http://wb5rmg.wordpress.com ...

Thanks again to all who contributed to this effort.

Hi Bill,

Congrats on a successful test flight, and I hope your HF beacon manages to do as well crossing the drink by 'n by. I did copy the CW, but no joy on Domino or Hell here in CO. Just a G5RV, however.

Excellent news re the recovery. I guess you're lucky that it landed close enough to a road that the folks saw it before the artillery practice began!

Re nasty landing sites:

One of our CU Gateway to Space flights (the one with cockroaches) landed right next to an active missile silo. I guess the folks in there observed all those vehicles with strange appendages and the crown of Birkenstock-shod undergrads storming the site, which prompted the arrival of two black SUVs with gun ports and gov't tags to stop on by. Sure glad we had a Sheriff's LT on the T&R team to 'splain it to 'em!

Another was on a buffalo ranch. Thanks to the rancher for training the recovery team on proper buffalo etiquette :=P.

More recently, we landed about 100 ft from the base of wind power turbine that had 150-ft long blades!

I'm bringing up this topic again?

Reason stating is Now Google has sent a phone up via a balloon!

While the whatever factor again and have we not discovered that phones
on balloons were illegal did we not?

But the part that makes me nervous is the statement made at the very end
on what Google Plans on doing with this.

Hi James, wow that was a close call for sure....I have a photo somewhere that looks exactly like the "nearly a disaster photo" of yours....mine was dangling about 1 foot above Lake Guntersville from a tree limb 10 feet off shore. Great stuff.

After seeing all the stories, I think we'll need a top 100 worst spots....and Mike, I sure do remember the "how to keep a pack of Buffalo happy" training by the rancher before entering the field for the recovery. As I recall he had a bucket of "Buffalo Treats" that were compressed hay the size of coke cans to distract them if they got too skittish. The most important part of his training was that buffalo when spooked will stampede over anyone in their way and right through miles and miles of barbed wire fences before stopping.

Domino or Hell here in CO. Just a G5RV, however.

Excellent news re the recovery. I guess you're lucky that it landed close
enough to a road that the folks saw it before the artillery practice began!

Re nasty landing sites:

One of our CU Gateway to Space flights (the one with cockroaches) landed right
next to an active missile silo. I guess the folks in there observed all those
vehicles with strange appendages and the crown of Birkenstock-shod undergrads

storming the site, which prompted the arrival of two black SUVs with gun ports and gov't tags to stop on by. Sure glad we had a Sheriff's LT on the T&R team to 'splain it to 'em!

Another was on a buffalo ranch. Thanks to the rancher for training the recovery team on proper buffalo etiquette :=P.

More recently, we landed about 100 ft from the base of wind power turbine that had 150-ft long blades!

From: Robert Rochte
Topic: 9084 Message: 9092

I never received a photo of my balloon that landed across a rural road in Ohio and was described by the local sheriff as looking like "smoke across the road" (it was at night and the translucent envelope of the still-inflated solar Montgolfiere stretched from one side of the road to the other). Fortunately, the payload was just off to the side of the road and was returned unscathed (I collected it from the trunk of the sheriff's patrol car a few days later).

My most scenic recovery photo - after the payload had taken a week-long holiday down the length of Lake Erie - remains this one:

http://3.bp.blogspot.com/_Q-9xDZflyLU/RuGlV6asEGI/AAAAAAAAAA0/0E9_7POCpsI/s1600-h/07Sept2007a.jpg

On a completely unrelated note, I have a part-15 "Hifer" beacon on the air right now, somewhere around 13.556Mhz. It is transmitting "GPA" using QRSS3. If anyone copies it, please let me know!

Great Photo Robert. Always seal your packages up like they are going to take a bath and sometimes they do even when you do not expect it.

While you are looking for Robert's GPA HiFer, give a listen for my HiFer at 13.563, in CW transmitting SZX.

Attachments: 2 described; binary payloads are missing from this source WARC

Hi Everyone,

I've used it many many times and got the Idea from Bill ELK about using bubble wrap to insulate a payload. I just came across this stuff and I wonder how much better it may be?

It is a small bubble bubble wrap, but has like a mylar foil on both sides also. so it also block the radiation of heat loss from happening. At a night time flight it has to be better. But day time i wonder how much solar heating through the bubbles we now wouldn't get..

It would be a neat experiment to fly two payloads one with clear bubbles and one with the foil,

do it day and night, hmmm?

It's called Reflectix and used a lot in the HVAC industry, as well as shipping products. They have on their web page examples on how it's much better than styrofoam for heat loss prevention.

9095. Extracting Balloon flights from APRS-IS

Yahoo group: GPSL (2009 — 2010)
Date: 2010-12-27 17:43:17 UTC
From: Jerry Gable
Topic: 9095 Message: 9095

Since late November I have had a program running that extracts balloon flights from the APRS-IS stream.

You can see the preliminary output here: http://www.s3research.com/flightdata/

Except for Christmas weekend there has been at least one detected flight every weekend.

It updates once a minute so you should see it update any active flights.

To keep down the amount of data to process it only looks at packets that use the Balloon or Rocket symbols (letter O and alternate table letter O). To eliminate people driving around in their cars with the balloon symbol and the few hot air balloons, they have to reach 20,000 feet before I tag them as an actual balloon flight.

Now the question is, is this of interest to anyone? Should I continue to work on it? Any suggestions for changes?

Jerry

Yes! That is an excellent idea. I've often thought it would be fun to have some method to search out balloon flights around the country and this is a good idea.

One thought is that 20K' might be a little high. There will be a lull in the first number of minutes before a HAB flight in identified. And, another thing is that high powered rocket fliers are increasingly using GPS based onboard transmitters to track and find their rockets. More may be using the 70cm band due to the shorter length transmitter antenna but there are 2 meter transmitters such as the Bid Red Bee.<http://www.bigredbee.com/index.htm>
There are rocket launches 'most every weekend around the country, too.

I like what you done!

That is a pretty cool exercise in data mining.

Unfortunately many groups still don't use the balloon symbol regularly, esp. on alternate payloads. If you wanted to process a fuller APRS-IS data stream, one could find the other flights with some relatively simple rules. One that comes to mind is any moving station that exceeds 45,000 ft and has a speed less than 200 kts. That should eliminate aircraft and any satellite objects. With a little thought, you may be able to design a APRS-IS filter to reduce the processing load (getting rid of wx data comes to mind).

Great idea, I also think 20,000ft is a little high.

A group of us use ANSRVR (similar to CQSRVR) to alert each other to balloon launches, would be handy if your system could send alerts through that.

I did my initial testing with the full APRS-IS data stream and the capture is able to deal with that. A simple filter that would eliminate weather and a few other streams would get the workload down to a reasonable number.

The biggest issue with detecting balloons is the out of order/ duplicate packets. The flights that I have captured all have many duplicates and packets that are out of order by several minutes. Hitting multiple repeaters and i-gates is a problem. This makes detecting points in the flight difficult. I initially tried using 3 out of 5 packets with > 500ft/min rise as the launch marker. I gave up and decided to use the 20K feet limit. My first limit was 15K feet and that added another 50% hits for things that didn't seem to be balloons.

Right now I am keeping all of the packets that I receive in a database. As I gather data I will see if I can come up with a better flight detection algorithm. If nothing else, I could create a "Potential Flight" category that will get dropped if it doesn't make it to the 20K height.

Actually, it may not be problematic to keep the hot-air balloons as trackable on your page (maybe filtered separately). I've always wondered how many hot-air balloons use APRS for tracking. One of these days I'm going to get a local balloonist I've been working with to include regular APRS tracking of his flights - I'd like to know when he's airborne and where he's flying. He's got a ham license but hasn't gotten the equipment yet.

You might also take a look at what aprs.fi does for it's dupe filtering. It seems to do it by comparing the speed derived from two subsequent packets and if it's too high rejects the later one. Probably the site owner can tell you more details. It's not perfect but does a fair job.

I also hear that some private pilots that are also hams are using APRS so that their family can track them.

A couple weeks ago I happened to noticed an APRS station doing 180 mph at 13,000 ft just south of Oklahoma City.
I watched for a couple days as he made his way to Memphis then up to NJ. He originated in Southern Calif. He beaconed
his N-number, it was a Cessna 210 registered to a business in Ca. He got great coverage all across the US. I haven't seen
the plane move since the 11th of Dec.

Here's an opportunity to encourage everyone to set their balloon payloads to include hour/minute/second time stamps in their APRS positions. It makes post-flight analysis a lot easier when trying to sort data from multiple sources, and for stations following on APRS-IS to tell what is going on. OpenTracker and TinyTrak can be configured to do this. Here's an example from my car:

N9XTN-9>APOTC1,WIDE1-1,WIDE2-1,qAR,KE6DZD:/191727h4107.76N/09554.70W>038/021/A=001054
14.0V

I agree with Mark. Many of our BASE flight APRS transmissions reach the Internet out of order, leading to some amazing flight paths. Having the transmission time stamp included in the data string has been essential to getting the flight data back into proper chronological order.

Of the 8 flights in my limited database, 5 have timestamps and 3 don't.

I have a big Red Bee tracker and it doesn't have a timestamp. I just asked Greg to add altitude based path switching and he did that quickly so maybe he would be willing to add a timestamp also.

From my point of view the APRS is for tracking. Any data that I am interested in from the balloon I store on the balloon at a much higher data rate so the timestamp is really not required for me.

I agree with Mark. Many of our BASE flight APRS transmissions reach the Internet out of order, leading to some amazing flight paths. Having the transmission time stamp included in the data string has been essential to getting the flight data back into proper chronological order.

It makes post-flight analysis a lot easier when trying to sort data from multiple sources, and for stations following on APRS-IS to tell what is going on. OpenTracker and TinyTrak can be configured to do this. Here's an example from my car:

Most of the packets sent are either APRS position reports or Mic-E packets. Position reports can have a timestamp but it is optional. Mic-E packets do not have a position field.

I haven't seen any that encode the direct GPS packets yet.

Looking back through my log I came across reports from WSONDE-6 and WSONDE-7 They appear to be objects being sent by DJ7KL and are in the air now.

I am not currently decoding objects but it appears that I need to.

Does anyone know anything about these balloons? One looks like it went from ~1000 ft to 70K feet in a few minutes.

Jerry

But what if you don't get the payload back? :)

Seriously, though, being able to reconstruct a track after the fact from multiple data sources (including APRS-IS - that's why we fly our backup on 144.39) has helped us narrow our searches and diagnose what happened.

Joe....it likely would help keep internal heat inside, particularly for night flights....however, the clear stuff allows a greenhouse effect to occur from the solar radiation during the day and often my payloads stay above freezing throughout the flight with just 3 layers of small-cell bubblewrap. This stuff would be most useful for night flights as long as the foil doesn't detune the antenna or block the signal to the GPS receiver....I'd test for that before flying this stuff. You are right, this is a perfect student experiment to fly this stuff and another temp sensor with clear bubblewrap and plot the difference.

Subject: [GPSL] To: Bubble Wrap Bill, And Everyone Else

Hi Everyone,

I've used it many many times and got the Idea from Bill ELK about using bubble wrap to insulate a payload. I just came across this stuff and I wonder how much better it may be?

It is a small bubble bubble wrap, but has like a mylar foil on both sides also. so it also block the radiation of heat loss from happening. At a night time flight it has to be better. But day time i wonder how much solar heating through the bubbles we now wouldn't get..

It would be a neat experiment to fly two payloads one with clear bubbles and one with the foil,

do it day and night, hmmm?

It's called Reflectix and used a lot in the HVAC industry, as well as shipping products. They have on their web page examples on how it's much better than styrofoam for heat loss prevention.

These look like radiosondes that someone is recoding into APRS data. Easier to do with their sondes.
